About the Author

The Science of Correct Thinking

Author's Preface

Introduction

I. IDEA AND TERM

1. NATURE OF THE IDEA
2. KINDS OF IDEAS
3. UNIVERSALS
4. TERMS
5. DEFINITION AND DIVISION

II. JUDGMENT AND PROPOSITION

6. NATURE OF JUDGMENT AND PROPOSITION
7. GENERAL TYPES OF PROPOSITIONS
8. SPECIAL TYPES OF PROPOSITIONS
9. OPPOSITION OF PROPOSITIONS
10. EDUCTIONS

III. INFERENCE AND ARGUMENTATION: DEDUCTION

11. NATURE OF REASONING
12. CATEGORICAL SYLLOGISM
13. SYLLOGISTIC FIGURES AND MOODS
14. VARIETIES OF CATEGORICAL SYLLOGISMS
15. HYPOTHETICAL SYLLOGISMS
16. VARIATIONS OF THE SYLLOGISM

IV. INFERENCE AND ARGUMENTATION: INDUCTION

17. NATURE OF INDUCTION

18. THE LOGICAL FOUNDATION OF INDUCTION
19. INDUCTIVE METHOD
20. PROBABILITY
21. FALLACIES
- GLOSSARY

Reality and the Mind

Preface

I. THE POSSIBILITY OF VALID KNOWLEDGE

1. STATEMENT OF THE PROBLEM
2. IDEAS FUNDAMENTAL TO THE PROBLEM
3. SPECIFICATION OF THE PROBLEM
4. SKEPTICISM AND DESCARTES' DOUBT
5. THE PRIMARY TRUTHS

II. THE VALIDITY OF HUMAN KNOWLEDGE

6. THE TRUTH-VALUE OF CONSCIOUSNESS
7. DEVELOPMENT TO IDEALISM
8. RETURN TO REALISM
9. FALLACY OF IDEALISM
10. EXTRA-MENTAL AND EXTRA-EGO REALITY
11. REPRESENTATIVE AND PRESENTATIVE REALISM
12. CRITICAL PRESENTATIVE REALISM
13. THE PROBLEM OF THE UNIVERSALS
14. THE TRUTH-VALUE OF THE UNIVERSALS
15. THE TRUTH-VALUE OF NECESSARY JUDGMENTS
16. THE CRITERION OF TRUTH
17. FALSE CRITERIA OF TRUTH
18. THE TRUTH-VALUE OF REASONING
19. RECAPITULATION
- GLOSSARY OF TERMS

The Domain of Being

Author's Preface

I. BEING AND ITS PRIMARY DETERMINATIONS

1. SCIENCE, METAPHYSICS, ONTOLOGY
2. THE CONCEPT OF BEING
3. KINDS OF BEING
4. THE CONTRACTION OF BEING
5. THE SUPREME PRINCIPLES
6. ACT AND POTENCY
7. ULTIMATE GROUND OF POSSIBILITY
8. CHANGE AND MOTUS
9. THE PRINCIPLE OF CHANGE
10. ESSENCE AND EXISTENCE

II. THE TRANSCENDENTAL ATTRIBUTES OF BEING

11. BEING AND ONENESS
12. IDENTITY AND DISTINCTION
13. BEING AND TRUTH
14. BEING AND GOODNESS
15. BEING AND BEAUTY

III. THE SUPREME CATEGORIES

16. THE CATEGORIES
 17. SUBSTANCE AND ACCIDENT
 18. ESSENCE, NATURE, HYPOSTASIS, PERSON
 19. QUALITY
 20. RELATION
 21. ACTION, REACTION: CAUSE, EFFECT
 22. EFFICIENT CAUSALITY
 23. FINAL CAUSALITY
- GLOSSARY OF TERMS

From Aether to Cosmos

Author's Preface

I. THE PHYSICAL CONSTITUTION OF BODIES

1. COSMOLOGY
2. THE ELEMENTS
3. ATOMS AND SUBATOMIC PARTICLES

4. THE TRANSMUTATION OF ELEMENTS
5. THE STRUCTURE OF MATTER
- II. THE GENERAL PROPERTIES OF BODIES
 6. QUANTITY AND EXTENSION
 7. PLACE AND SPACE
 8. QUALITY AND ACTIVITY
 9. MOVEMENT AND TIME
- III. THE ESSENTIAL CONSTITUTION OF BODIES
 10. THE PROBLEM OF BODILY ESSENCE
 11. DYNAMISM AND ATOMISM
 12. HYLOMORPHISM
 13. THE HYLOMORPHIC THEORY
 14. HYLOSYSTEMISM
- IV. THE UNIVERSE OF BODIES
 15. HEAVEN AND EARTH
 16. THE COSMOS
 17. CAUSALITY AND LAW
 18. RELATIVITY
 19. BEGINNING AND END
- GLOSSARY OF TERMS

The Whole Man

Author's Preface

1. NATURE AND SCOPE OF PSYCHOLOGY
2. MAN: AN ORGANISM
3. THE NERVOUS SYSTEM
4. THE SOMESTHETIC SENSES
5. SMELL, TASTE, HEARING
6. SIGHT
7. CENTRAL OR SYNTHETIC SENSE
8. IMAGINATION
9. MEMORY
10. INSTINCT

11. SENSUOUS APPETENCY
 12. INTELLECTION
 13. THE ORIGIN OF IDEAS
 14. ARISTOTELIAN IDEOGENY
 15. VOLITION
 16. FREEDOM OF WILL
 17. CONSCIOUSNESS
 18. EXTRANORMAL MENTAL STATES
 19. THE VITAL PRINCIPLE
 20. THE SOUL OF MAN
 21. THE HUMAN PERSON
 22. THE ORIGIN OF MAN
 23. THE DESTINY OF MAN
- GLOSSARY

Man and Morals

Preface

I. GENERAL ETHICS

1. NOTION AND SCOPE OF ETHICS
2. THE HUMAN ACT
3. VOLUNTARINESS
4. IMPEDIMENTS TO HUMAN ACTS
5. ENDS OF THE HUMAN ACT
6. MAN'S ULTIMATE END
7. THE NORM OF MORALITY
8. FALSE NORMS OF MORALITY
9. THE MORAL LAW
10. OBLIGATION AND SANCTION
11. VIRTUE AND VICE
12. RIGHTS AND DUTIES

II. SPECIAL ETHICS

13. GOD AND MAN
14. DUTIES OF LOVE

15. DUTIES OF JUSTICE
16. RIGHT OF OWNERSHIP
17. TITLES TO PROPERTY
18. WORK AND WAGES
19. DOMESTIC SOCIETY
20. CIVIL SOCIETY
21. GOVERNMENT
22. INTERNATIONAL SOCIETY
23. INTERNATIONAL COMMUNISM
- GLOSSARY

God and His Creatures

Preface

I. THE EXISTENCE OF GOD

1. NOTION AND SCOPE
2. FIRST PRINCIPLES
3. THE POSSIBILITY OF PROOF
4. CHANGE
5. DESIGN
6. CONTINGENCY AND CAUSALITY
7. LIFE AND PERFECTION
8. OPPOSING VIEWS

II. THE NATURE OF GOD

9. GOD'S ESSENCE
10. SIMPLICITY, INFINITY, UNICITY
11. IMMUTABILITY, ETERNITY, IMMENSITY
12. GOD'S INTELLECT AND WILL
13. OMNIPOTENCE AND CREATION
14. CONSERVATION AND CONCURRENCE
15. PROVIDENCE AND GOVERNANCE

ABOUT THE AUTHOR

Celestine N. Bittle (1884 - 1960).

An Alumnus Of St. Lawrence Seminary High School, Mount Calvary, Father Bittle Was A Noted Author And Philosopher. He Served As Military Chaplain, And As The First Principal Of Messmer High School In Milwaukee.

In 1925, with the support of Archbishop Sebastian Messmer, Monsignor George Meyer began to work at establishing a Catholic high school on the north side of Milwaukee. The high school opened the very next year with 166 students in the St. Elizabeth School building on the corner of 1st and Burleigh. At that time, it was called Diocesan High School. A Capuchin, Fr. Celestine Bittle, was the first principal and six religious sisters comprised the faculty.

THE SCIENCE OF CORRECT THINKING

LOGIC

AUTHOR'S PREFACE

Our present day, is rather disputatious. New ideas and theories in economics, science, statecraft, philosophy, and religion clamor for recognition. Some of these issues have been slow in coming to the fore; others have been violently thrust to the surface in the catastrophic upheaval of the World War. They will demand attention for decades to come, and they cannot be side-stepped. From soapbox and rostrum, through the medium of the press and the radio, these problems are filtering from the higher levels of the intellectuals down to the common people.

Many of these issues will have to be decided by the rising generation. They must reason their way through the new theories and the novel experiments. That a knowledge of sound principles is a prime requisite for this, goes without saying; and that a thorough understanding of the science of correct thinking should prove a valuable aid in this task, is equally certain. Far too many errors in the solution of problems are due to loose reasoning and to an ignorance of the laws which govern our mental operations. We must be able to think logically before we can act logically. Hence, the study of logic should be time well spent for the educated

person and particularly for the student, for they will be the leaders of tomorrow. Books on philosophy, and therefore also on logic, are usually of two types: textbooks and monographs. Most textbooks are so brief and skeletonized that the ordinary reader fails to grasp the full significance and value of the material; monographs, on the other hand, are so complicated and technical, that they appeal only to the professor and the professional.

Yet it should not be impossible to combine the advantages and avoid the disadvantages of both types of books: relative completeness of material, with the absence of undue complication and technicality. The author has attempted to treat this most fundamental department of philosophy along these lines. For this purpose he has endeavored to use simple language and copious illustrations, so as to render the subject understandable. Philosophy cannot be made easy, but it certainly can be made less difficult. At the same time, the technical side of logic has not been omitted, but has been built up in gradual stages, so that the mind of the student can grow with the subject. The more controversial points have been left aside as being less in keeping with the positive purpose intended; after the reader has grasped the fundamentals, he should be able to wrestle with the monographs.

Since logic treats of the purely mental operations of ideas, judgments, and inferences, which always remain the same, no radical departure from traditional teaching need be expected. Nor can a large amount of explanations, definitions, divisions, and rules be avoided in a subject of this kind; they are a necessary burden which cannot be

shirked without detriment to a proper understanding of the nature and function of these operations. In explaining the syllogistic figures and moods the author has used a set of symbols of his own devising; he has found them very effective in his work in the classroom, and he hopes they will be equally helpful in enabling the reader to understand this difficult but important part of logic. To make the subject more readable, the ordinary textbook arrangement was dropped in favor of the chapter form. It was hoped that in this way the book would be made palatable not only to the student, but also to any person desirous of self-education. The book is intended, therefore, as a textbook, if so desired, or as supplementary reading in classwork, or as an introduction to philosophy for the general reader. In any case, a well-grounded knowledge in the science of correct thinking should be a valuable asset in these troublous times confronting the nation.

February 22, 1935.

INTRODUCTION

PHILOSOPHY AND LOGIC

We live in a mechanical age. During the last century and a half the natural sciences have received a tremendous impetus; their scope of investigation has been widened to a remarkable extent; their achievements have been of an extraordinary nature; and their material benefits to mankind have become really phenomenal. Thinkers and investigators have turned more and more to these positive sciences as the great field in which to apply their powers of research, with the result that they have come to look upon them as the only legitimate source of knowledge, since they present facts which alone can be proved by the exact demonstration of observation and experiment. The telescope, the microscope, the test tube — these have become the standard and measurement of truth. Nothing else has real value. They greet the mention of philosophy with a cynical smile or at best with the tolerance of a deprecating shrug of the shoulders. Philosophy, to them, is nothing but the vaporizations of speculative dreamers; it deserves no serious consideration as a science.

PHILOSOPHY AND SCIENCE

This attitude is based upon an ignorance of the nature and function of philosophy. Philosophy and the exact sciences are not in opposition to each other; their origin and scope are fundamentally the same. Both originate from the unquenchable thirst of the human mind for a deeper knowledge of the world within and around us. This, in the individual as well as in the race, begins with birth and ends only with death. Knowledge starts in the senses and finishes in reason. The child obtains one sense impression after the other and gradually recognizes the relations between things. Soon its mind asks the eternal questions of "How ?" and "Why ?"; it insists on knowing the hidden causes. As the years roll on, the fund of accumulated facts grows incessantly, and the mind's demand for an adequate explanation proceeds apace. A merely superficial knowledge of the phenomena of nature no longer suffices; the mind endeavors to break through the surface of things and appearances, in order to study the deeper causes of nature and its workings. This is the starting point of the natural sciences.

The mind accepts the world at large as a great fact and portions it out among the various sciences. Each science has its own particular field of research. Astronomy studies the outside universe; physics studies the forces of nature in its manifold operations; chemistry studies the elements and their compounds; botany studies the plants; zoology studies the animals; physiology studies man in his bodily construction and the functioning of his organs; biology

studies life and its development; and so with every special science.

Science does not desire a mere enumeration of facts; it seeks to discover the underlying principles, the causes and the laws behind these facts, so as to explain them and arrange them into a comprehensive system of knowledge. For the phenomena of nature in a particular field are not isolated and independent, but interrelated and interdependent. It is the scope of science to discover these relations and to formulate them into laws of universal value which will apply at all times and in all places and under all conditions. A few examples will illustrate the point. Mankind has always known lightning and its effects; but it was only after the discovery of electricity and the famous kite experiment of Benjamin Franklin that the physical nature of lightning became clear. Water had always been merely water to people, until science revealed the fact that it consists of one part oxygen and two parts hydrogen. Nations have always experienced epidemics; the discovery of disease-bearing germs, however, explains the nature of contagious infection and gave rise to the new science of medical bacteriology. Everybody has observed the fall of bodies; but a scientific knowledge of this phenomenon was only attained when Newton attributed it to the attractive force of the earth, and scientists formulated the law of accelerated motion. These are only isolated instances, but they show how the mind of man is dissatisfied with commonplace explanations and tends to delve beneath the surface of phenomena to discover their hidden relations and causes.

Now, philosophy is based on this same innate thirst of the mind for deeper knowledge. There are many problems which lie beyond the reach even of science. Why should the mind of man not try to solve them? If science with its observation and experiment cannot reach an ultimate explanation, might not reason find a way? After all, science must also use reason to prove its conclusions, and philosophy simply goes a step farther. Science presupposes many things which philosophy would fain investigate. If science has the right to analyze nature and reduce its many phenomena to their simpler elements and laws, thereby increasing man's knowledge, who would gainsay to philosophy the right to strive for a still greater unification and systematization of the laws and principles of nature? It were different if philosophy refused to accept the proved conclusions of science; but that is not the case. Philosophy accepts the legitimate findings of science and then pushes its investigation still farther into the regions of the unknown, thereby attempting to widen the boundary line of knowledge. Philosophy is thus an extension of science. Chemistry, for instance, has discovered over ninety different elements, ranging from hydrogen to uranium, and these compose all the different kinds of bodies in the world; this is as far as science can go. Here the problem naturally arises: Since all these elements consist of matter, why their essential difference among themselves? Are they composed again of atoms, electrons, protons? What forms the ultimate constitution of bodies? Again, many sciences, like biology, botany, zoology, etc., treat of living things and accept life as a given reality. But what, precisely, is life? Whence does and

can it originate? Is it fundamentally distinct from the chemical elements that constitute the body? Is it merely a force, or is it a substantial principle? Experimental psychology makes a special study of man's mind in all its moods, states, and operations. However, what is the nature of the mind? Is it material or immaterial? Accidental or substantial? What is the nature of the soul? Mortal or immortal? Astronomy and astrophysics make the universe their special object of research. But whence the stars? What is the origin of the world? Is it eternal? Does chance account for the existence and orderliness of its arrangement? Must it have been created? Is there a God? If so, who and what is He? Anthropology treats of man. Now, is man a responsible agent, endowed with free will, or merely a sublimated ape? Is there a fundamental distinction between right and wrong? Is expediency or divine law the norm which must govern man's actions?

The very foundations of the natural sciences may be questioned. The Principle of Causality — has it objective value or is it merely a figment of our mind? The laws of nature — are they constant and immutable or are they in a continual state of change like nature itself? Can the mind really know truth? What is truth? Is it based on permanent realities or does it shift with time and place? How can we know that our senses give us a true picture of the surrounding world and that the mind can reach the hidden cause behind the phenomena of the senses? If these questions cannot be satisfactorily answered, then the very foundations of the sciences are insecure and the entire

systematic structure built upon them will collapse like a house of cards.

These are not idle questions. They are important, vital, all-embracing, and affect every part of the natural sciences, from their first principles down to their last conclusions. These problems are worthy of every attempt at solution, and the human mind has the right and the duty to find the answers with the aid of its reason. That is the purpose and function of philosophy. It is the super-science which seeks to bring all the special sciences and their scattered data into a higher system of unity — a veritable world-synthesis. Philosophy, therefore, begins where science ends. It is fundamental to all sciences, delving down into the deepest and ultimate reasons and causes of nature, thereby endeavoring, so far as human intelligence can reach, to solve the riddles of the universe. The right of the human mind to search for truth gives to philosophy its right to existence.

From the above it will be clear how we must define philosophy. *Philosophy* (from the Greek *φιλεῖν*, to love, and *σοφία*, wisdom; 'love of wisdom') is *the science of beings in their ultimate reasons, causes, and principles, acquired by the aid of human reason alone*. A brief explanation will clarify this definition.

Philosophy is a *science*. It is not based on mere opinions or theories or hypotheses, but is certain knowledge derived from reasoned demonstrations of causes and reduced to a system. Philosophy is a 'science of *beings*'; that is, of all things which can be reached by the human mind. This includes man, the world, God; everything that is, or

becomes, or is known. Other sciences have as their special field of research some particular province of natural phenomena but philosophy has as its object the whole universe and the Supreme Being. Philosophy is the 'science of beings *in their ultimate reasons, causes, and principles.*' A 'reason' is that by means of which a thing is known and can be understood; a 'cause' is that which contributes in some positive manner toward the production of a thing; a 'principle' is that from which something proceeds. The other sciences give the proximate causes of things, while philosophy searches for the *ultimate* reasons and causes and principles. Thus, physiology treats of the organs and functions of the human body, while philosophy explains the nature of man in his body and soul, in his vital principle and its connection with 'the body. In other words, philosophy endeavors to understand and explain the fundamental essences of things. Finally, philosophy is the 'science of beings in their ultimate reasons, causes and principles, *acquired by the aid of human reason alone.*' This means that philosophy does not base its knowledge on authority, but solely on the reasoning power of the human mind. Divine revelation, therefore, is formally excluded as a source of information in philosophy, although it can and should assist the mind of man by pointing out the proper direction for the philosophic solution of a problem along purely natural lines.

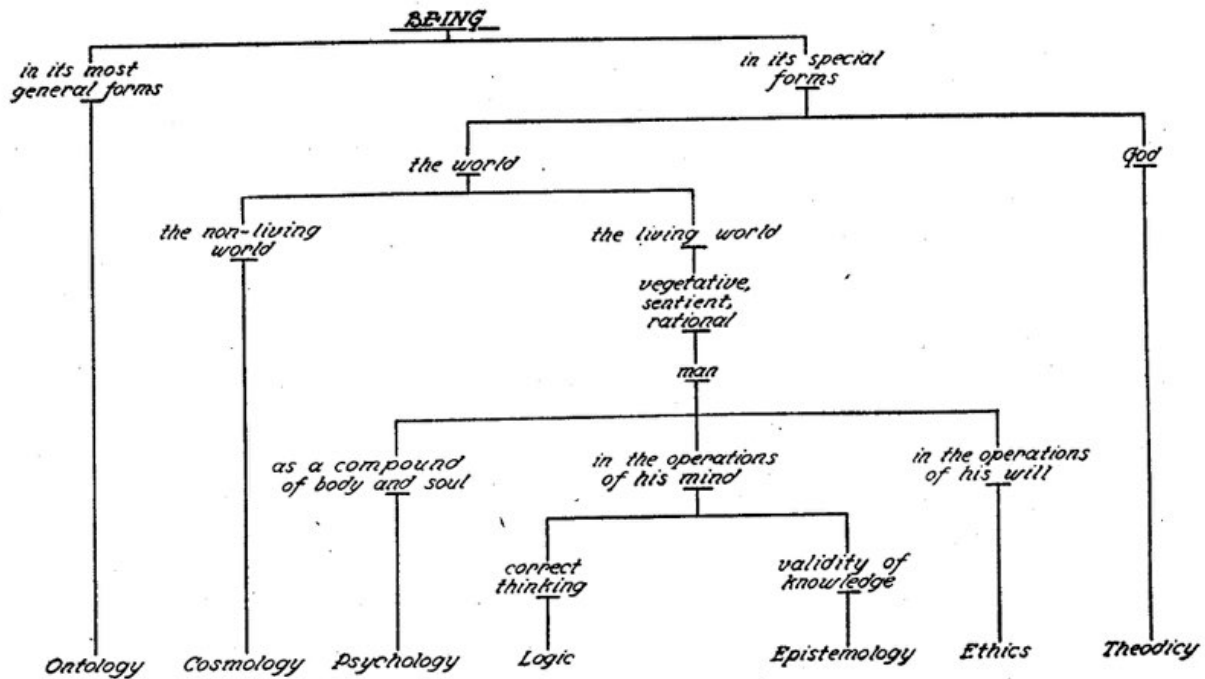

To sum up: the material object of philosophy is all being in the widest sense of the term; its formal object is all being in its ultimate reasons, causes, and principles, studied in the light of human reason.

What are the benefits to be derived from a knowledge of philosophy?

From the standpoint of personal advantage, the searcher after truth will find in philosophy a treasure-trove of priceless information, ranging all the way from the atom and the cell to man and the stars and the universe and God. No province of truth is foreign to philosophy. While the various sciences are as so many facets that reflect a brilliant ray of light, philosophy is the jewel that unites all the facets into a harmonious burst of glorious truth. As the sciences in their unceasing research discover the single facts of nature and express them in unchanging laws, thereby simplifying their understanding, so philosophy in turn investigates the findings of the single sciences, discovers the principles and laws common to them all, and unites the various sciences and their conclusions into the highest synthesis possible to the human mind on the basis of reason alone. Philosophy is the unification and systematization of all important knowledge within the domain of reason. If the knowledge of the single sciences is an acquisition worth more than all material comfort and gain, then the knowledge of philosophy, the super-science summarizing and unifying them, is proportionately richer and higher in value: it is the supreme achievement of the human intellect in a purely natural way. So far as the arrangement and sequence of these various departments of philosophy are concerned, each has its advantages and disadvantages. Some philosophers contend that philosophy should follow the natural course of human thought and investigation. We should begin with the world around us

(cosmology); then consider man himself (psychology); then study the inner workings of the mind (logic, epistemology) and will (ethics); then investigate being in itself (ontology); and finally contemplate God (theodicy). Others object to this arrangement on the score that the philosophy of being in general (ontology) must precede the philosophy of particular beings, and a person must first learn to think correctly (logic) and be assured of the validity of his knowledge (epistemology) before he begins to philosophize. The fact is simply that the entire division of philosophy into departments, though based on good grounds, is inadequate, because no department is altogether exclusive of the other; this makes a certain amount of repetition of ideas and principles inevitable, the field of investigation being so extensive that it cannot possibly be covered without passing and re-passing the same lines. This will always remain a practical difficulty which can only be solved by the method of treatment.

One of the best arrangements is to begin with logic, the science of correct thinking, because correct thinking is necessary for every department of philosophy. The next step would be epistemology, the science of the validity of human knowledge, because only if we are sure that we can attain truth will philosophy rest upon a solid basis.

And since everything that philosophy investigates is being in some form or other, ontology, the science of being in general, should be of great help in understanding the special kinds of being. Now the mind is ready to study the problems of the world in inorganic nature, and that leads to cosmology. The study of living beings will be next in order; and since man has vegetation (plant life), sensation (animal life), and reasoning (rational life), psychology, the science of life, follows as a matter of course. From the study of inorganic and organic nature to the investigation of the existence and nature of God is but a natural step; hence theodicy, the science of God. Ethics should actually follow psychology, since man's will is a part of his rational nature, but morality and responsibility are meaningless without a knowledge of God, the Supreme Lawgiver, and therefore ethics takes the last, but not the least, position in

philosophy. This arrangement is not perfect, because the rather abstract departments of logic, epistemology, and ontology are in the lead; but here, as in many other instances, it may be best to acquire a thorough understanding of the technique and the fundamentals of the science before attempting to put them into play. The first step, then, in the study of philosophy will be an investigation into the *laws of correct thinking* and into the foundations of knowledge. That is the beginning of wisdom and of truth.

PHILOSOPHY AND LOGIC

Truth is the object of our thinking; it also marks the extent and the limitation of our thinking powers. We attain truth when our thinking (judgment) corresponds with the reality of things; and, since every being contains something that can be known as true, truth is as wide as being, and that comprises everything that is actual or possible.

Many truths are quite apparent. I gaze out of my window and see the sun in the sky; I know that it is day. I see a collie frisking over the neighboring lawn; I know that he is alive. I notice a patch of snow on the embankment; I know that winter is near. Experience makes these truths obvious, and I need no complicated reasoning process to establish them. But the attainment of truth is not always so simple. Does the sun move around the earth, or the earth around the sun? Is a monarchy or republic the better form of government? Has man a soul distinct from his body and, if so, is it immortal? Is there a Supreme Being above and

beyond the physical world? Is crime the result of a disease or of a perverted free will? Is evolution a fact or a fancy? Merely to state such questions is enough to illustrate the fact that the attainment of some truths presents many difficulties which can only be resolved by a long, careful, and painstaking research.

Now, to be reasonably sure of success in such an undertaking, we must be sure of every step in the process of thinking from beginning to end; a mistake, or even a serious doubt, anywhere along the line would vitiate the end result and make the assurance of truth impossible. Correct thinking is a necessity in any problem that confronts our mind. It makes no difference whether we discuss a problem of politics or economics or science or law or art or history or philosophy or religion; nor does it matter whether we argue the respective merits of automobiles or sports or persons or buildings or card games or hats or shoes or other commonplaces of everyday life: reasoning enters into every such argumentation; thinking is the basis of reasoning, and to know the laws of correct thinking will, therefore, be a great help in avoiding errors and in finding the truth. The widespread differences of opinion among men concerning the most vital problems prove the importance of clear thinking. Most arguments and discussions would not be so fruitless if the principles of correct thinking were better understood and applied. It is the function of logic to supply this knowledge and its application. The science of logic is not intended as a sort of parade ground for mental gymnastics, where the mind can disport itself in quibbles and subtle distinctions in order to

squirm out of some disagreeable conclusion of fact or theory; its purpose is to assist the mind honestly in discovering and attaining truth wherever it can be found. For *logic is the science of those principles, laws, and methods which the mind of man in its thinking must follow for the accurate and secure attainment of truth.*

Every normal person possesses native logical powers; this is no more than to say that all of us can think and reason and distinguish truth from error without special training in logic. The child's eternal question "Why?" shows this; it demands an explanation and a reason. The ordinary man of the street and the unlettered savage will often enter into lengthy discussions and argumentations, and they frequently display a remarkable sharpness of wit. But they are restricted to problems of an easier and simpler nature; deeper and more complicated problems are beyond their reach. It is a pitiful spectacle indeed to see even cultured men, high in science and business and statecraft, flounder through a discussion in a most deplorable fashion, once they leave their own specialized field, simply because they are practically ignorant of the principles, laws, and methods of correct thinking and lack a training in logic.

In order to proceed safely and efficiently in the solution of an intricate problem, we must have a thorough knowledge of the mind in its various operations, the elements that enter into the making of correct judgments and arguments, the rules that govern our reasoning, and the force of the different methods used in proving truth. Furthermore, our mind must be trained in the proper use of its own powers. The difference between a person with

merely native logical talents and a person with trained logical talents, is the difference between an amateur and a professional; in some cases the amateur may by sheer brilliance of mind achieve great results, but as a rule it is the trained professional who forges his way to the top. Occasionally, the ordinary driver of an automobile may acquire a wide knowledge of his car and its functionings, but usually only the trained mechanic knows all the details of construction and operation necessary to detect and repair the damaged parts and to keep the car in smooth running order. The same is true in every line of human endeavor, and this is also the case with the mind in its search for truth. The scientist and the philosopher must know how to use the tools of his craft and train himself in their proper manipulation. Genius, perhaps, is born. Scientific training, however, often makes the mediocre mind great. Dullards, of course, are failures everywhere.

From the above it will be plain that there are two kinds of logic, *natural* and *scientific*. Natural logic is what is called, in popular parlance, common sense. Scientific logic, on the other hand, is natural logic trained and developed to expertness by means of a well-grounded knowledge of the principles, laws, and methods which underlie the various operations of the mind in the attainment of truth. The study of logic is neither as easy nor as entertaining as the reading of a novel; it demands earnest attention, deep concentration, and persistent practice: but its value is inestimable in searching for the true solution of the manifold problems that confront the human mind. As such,

therefore, it deserves our serious consideration. Difficulties, of course, there are; but practice, here also, makes perfect.

The question has been asked: "Is logic a science or an art?" It is both. In as much as it consists of a comprehensive body of established principles and laws with their legitimate conclusions, woven together into a unified system, it is a *science*; in as much as the mastery of its technique enables the mind to pursue truth in an easy, orderly, and safe manner its purpose is practical and it is, in a wider sense, an art. After all, logic is not intended to be merely informative, to instruct; it is directive, aiming to assist the mind in the proper use of its powers.

Since the ultimate purpose of logic is to assist the mind in the attainment of truth, all the operations and factors which concur to bring about this result must be studied. These are threefold: the *idea*, the *judgment*, the *inference*. Truth consists in the judgment. If I state 'The day is warm,' and it is actually warm, then I state a truth; if it were cold, the statement would be an untruth. Therefore judgments must be analyzed in logic. But judgments consist of ideas, since the ideas form the elements of a judgment. Hence ideas must also be studied in logic. Most problems, however, cannot be solved by merely making a simple statement; to solve them a number of judgments must be compared and linked together in some system of argumentation or inference; in such cases we have a chain of ideas and judgments leading to a final and conclusive judgment containing the truth desired. Here is a skeletonized example: 'Man's body is a living compound; a

living compound can be dissolved into its parts; a living compound, dissolved into its parts, dies; therefore man's body dies.' Hence, the various kinds of argumentations and inferences also belong to the subject matter of logic. Furthermore, since there are two scientific methods which can be employed in the search and attainment of truth, 'deduction' and 'induction,' logic will also have to treat of these, because these methods are of particular value in building up the various sciences. Here we have, then, the natural division of the subject matter of logic: *idea, judgment, deductive and inductive inference*. They will be treated in this order.

SUMMARY OF INTRODUCTION

1. The apathy of scientists against philosophy is due to their ignorance of its nature and function. Science and philosophy have the same origin and scope — a deeper knowledge of the world within and around us, viewed in its underlying causes and principles. Philosophy is the extension of science.

The very *foundations of science* may be questioned. The Principle of Causality, the laws of nature, truth in general, the validity of human knowledge — these are philosophic problems affecting the foundations of science.

Philosophy is the science of beings in their ultimate reasons, causes, and principles, required by the aid of human reason alone.

The *benefits* from a knowledge of philosophy are great. It is the super-science which strives for the unification and

systematization of all important knowledge within the domain of reason: It enables the student to distinguish truth and error in all the conflicting and confusing opinions.

There are *seven departments* in philosophy: Logic, epistemology, ontology, cosmology, psychology, theodicy, and ethics. Logic is the most fundamental for acquiring knowledge and truth.

2. Truth is the object of thinking. Some truths are obvious; others are difficult of attainment. Correct thinking is a prime necessity in the solution of complicated problems, and logic enables us to think correctly. *Logic is the science of those principles, laws, and methods which the mind of man in its thinking, must follow for the accurate and secure attainment of truth.*

Ordinary man has natural logic or common sense. *Scientific* logic is natural logic trained and developed to expertness. Logic as a *science* consists of a comprehensive body of established principles and laws with their legitimate conclusions; logic as an art is the mastery of the technique embodied in these principles and laws.

Ideas, judgments, and inferences are the elements which enter into the operations of the mind in its attainment of truth. Scientific *methods* are also of importance for this purpose. Hence, logic will treat of ideas, judgments, deductive and inductive inferences.

PART I

IDEA AND TERM

Chapter 1

NATURE OF THE IDEA

IDEAS ARE THE BUILDING STONES OF KNOWLEDGE. THEY ARE THE elements that constitute judgments; and judgments express truth and error. This being the case, ideas in all their forms must be thoroughly understood by the philosopher, because no building can be solid unless its foundation is solid.

FORMATION OF IDEAS

The *process of forming ideas* will assist us in understanding their nature. All knowledge starts with the senses. Thus, sugar is presented as an object of perception to various senses. I see it — it is white; I feel it — it is hard and granular; I taste it — it is sweet. The combination of something 'white,' 'hard and granular,' and 'sweet' forms an image in the inner sense, the imagination and memory; and this image is retained even after the object itself, the actual sugar, is removed, because I can recall this image of sugar when I hear the word 'sugar.' In a similar way, when words like 'man,' 'automobile,' 'dog,' 'shovel,' 'mountain,' 'paper,' 'desk,' 'rain,' 'school,' 'hat,' 'New York,' 'Century of Progress Exposition,' 'George Washington,' 'Franklin D.

Roosevelt,' and so forth, are mentioned, I can recall their image as long as I have perceived them in fact or have heard or have read of them. Say "Rat!" to a terrier, and watch him start, prick up his ears, bark, and dash madly about in excitement; by means of his memory and imagination he revives the image of a rat that he has seen. This *image or phantasm* of the imagination is the first step in the formation of the idea.

Man, unlike the brute animal, does not stop at the mere reproduction of an image in his fancy. In the presence of this image man's mind begins to *think*. The intellect now gives its attention to this sense-image in order to make its own representation of the thing. It does this by a process of *abstraction*. An example will make this clearer. Through experience we come in contact with many beings which we designate by the common name 'man,' and we soon find that there are great differences between them. Some are small, some are large, some are of medium height; some are thin, some are stout; some are male, others are female; some are blond, others brunette, others black; in some the skin is white, in others yellow or brown or copper-colored or black; some are bearded, others not; some are virtuous, others vicious; some are phlegmatic, others lively; some are melancholy, others gay; some are normal in limb, others crippled; some are healthy, others diseased; and in age they range all the way from infancy to a century. The intellect, noticing and comparing these differences, soon discovers that many of these characteristics change or disappear, while others take their place. The intellect also perceives that certain characteristics remain intact through all

changes. Thus, all men have a body, which exists for itself, independent of all others; man, therefore, is a *bodily substance*. Like the plants, men take in food, assimilate it, grow, develop; man is a *living bodily substance*. Like the brutes, men see, hear, taste, smell, feel, imagine, remember; man is a sentient, living, bodily substance. Unlike them, men think, reason; man is a *rational, sentient, living, bodily substance*. And while the intellect perceives these characteristics, it also perceives that they are found in all men at all times and in all places, and without them 'man' would cease to be a 'man.' True, some men lose their sense of sight or hearing or taste or smell; but some form of sense-life is always retained, so that they are always *sentient* beings. Other characteristics may be more or less permanent, like arms, legs, bones, sex, etc.; but the intellect sees clearly that a 'man' would still be a 'man' without them; but 'man' must be a rational, sentient, living, bodily substance in order to be a 'man,' and the absence of *any one* of these would make him cease to be a 'man.' They are, therefore, the essential elements which constitute his human *nature*; they belong to man *as man*.

The intellect now strips (in thought, of course, not in reality) the individuals of all the nonessential qualities, retains the essential attributes only, and forms them into one *intellectual image* - man is a 'rational, sentient, living, bodily substance' — and since a 'sentient, living, bodily substance' is called an 'animal,' ***man is a rational animal***. This intellectual image of 'man' is the idea of 'man.'

Another example: We perceive an innumerable variety of plants which we call 'trees.' Disregarding all the differences

among them in size, age, color, texture, shape, seasonal change, sex, etc., the intellect retains merely the essential elements of the type, those found in *all* trees, and combines them into a single intellectual image or *idea*: namely, a 'tree' is a 'woody perennial plant with a single main stem, usually about at least ten feet high.' Again, we observe a multitude of 'circles' in rings, wheels, clock dials, coins, disks, drawings, etc., consisting of a variety of materials, sizes, and colors. Leaving all the differentiating peculiarities aside, the intellect seizes upon those elements which are common to them all and are necessary to them all as 'circles,' and forms these elements into the idea of the mathematical figure of a 'circle'; namely, 'a plane figure bounded by a single curved line called its circumference, every part of which is equally distant from a point within it, called the center.' Just as the idea of 'man' will fit each and every man. so the idea of 'tree' will fit each and every tree and the idea of 'circle' will apply to any and all circles, irrespective of their individual differences among themselves.

The intellect, of course, will make its own image or representation even of a *single* object, without comparing it with similar objects of its class. Thus, by merely putting my attention to the tree across the street and thinking about it, my intellect makes an idea of it, even if I never see another tree. This idea would be a real, though not the most complete, idea of a 'tree.' To become complete, I would have to compare this tree with others and make an intellectual image of the essence of all trees. Ideas or concepts are therefore twofold. In a wider sense an *idea is*

the simple intellectual apprehension of a thing, and it is made as soon as the intellect turns its attention to an object and makes its own image of the thing from the phantasm. In a narrower and stricter sense *an idea is the intellectual image of a thing*, representing its essential elements, and this is the product of an extensive and exhaustive comparison of a large number of objects belonging to the same class. Since, however, there is only a difference of degree between the idea in a wider and the idea in a stricter sense, our definition must include both. Hence we define the *idea (concept)* as the intellectual image or representation of a thing. This covers everything.

IDEA AND PHANTASM

There is always great danger of confusing the *phantasm* (sense-image) of the imagination with the idea (concept) of the intellect. There is a marked difference between the two, and from the very outset it is necessary to grasp and understand this difference very clearly. A close comparison of the two will remove any existing confusion.

For one thing, the phantasm is always something *concrete* and *individual*, fitting at the most only a few objects at one and the same time. We have indeed general images of a dog, a horse, a fish, a tree, a house, a polar bear, a man, etc.; but this is only because we retain in such an image the more striking and similar features of a class and ignore the distinguishing characteristics of the individuals. But we cannot form a phantasm or sense-image of all the members of a class, much less of a number of

classes taken together. For instance: Our imagination can make a general picture or phantasm of a 'roses' but it cannot make a phantasm that will fit a red rose and a white rose at the same time, because the image will fit either the red rose or the white rose but not both. Similarly, with the general phantasm of a 'tree,' what image can cover at the same time the wine-glass shape of an elm, the pyramidal shape of a fir, the spherical shape of a maple, and the fan-spread shape of a palm? So, too, with the general phantasm of a 'dog'; it cannot cover at the same time the peculiarities of a pekingese, a bulldog, a dachshund, and a mastiff. The same is true of the general phantasm of 'man'; no single image will adequately fit at the same time a baby, a ten-year-old boy, a twenty-year-old girl, Henry VIII, Napoleon, George Washington, and the more than fourscore-and-ten John D. Rockefeller. One can multiply such instances indefinitely. The phantasm becomes utterly inadequate and impossible, when applied to several classes at once. No single phantasm of a 'plant' can include at the same time the hollyhock, the pumpkin, the lily, the apple tree, the cedar, the hawthorn, the grapevine, the wistaria, etc. Much less can the single phantasm of a 'living being' cover the characteristics of an amoeba, a whale, a rose, an orange, a spider, an elephant, a chrysanthemum, a horse, an Indian, a Negro, Abraham Lincoln, etc. The reason is plain: the senses picture single concrete objects, and the imagination makes its images or phantasms from these sense pictures; therefore, the phantasm is also concrete and individual by nature.

The reverse is true of the idea or concept of the intellect: it is *universal* and for this reason applies with equal facility to an individual and to a class and to a number of classes. Take the idea of 'man' as a rational animal. By 'rational' we mean a being that has the power to think, and by 'animal' we mean a sentient being; by 'man' we therefore designate 'a sentient being that has the power to think.' This idea applies at the same time to every single human being taken individually and to all men taken as a class. It fits the infant, the child, the youth, the middle-aged and the old-aged person; it fits male and female; the Negro, the Caucasian, the Indian, the Chinese, the Polynesian; the large and the small, the slim and the stout, the healthy and the sick, the blond and the brunette. Now extend the class to include another. Take the idea of 'animal' as 'a sentient being.' This idea embraces all brutes and all men without any difficulty — the reptiles, the insects, the fishes, the birds, the mammals, and all men. The idea 'living being' will apply not only to all brutes and men, but will also include all plants of whatever nature and kind. Going a step farther in the scale of beings, we have the idea of 'substance,' by which we designate 'a being that exists in and by and for itself and does not need another as a subject in which to inhere.' This applies to all inorganic beings, metallic and nonmetallic, ranging from electrons and atoms up to the stars and the universe, and applies also to the entire field of the kingdom of plants, animals, and men. Not only does this idea fit the various classes as a whole but also each and every individual belonging to these classes. Here you have one of the main differences between an idea and a phantasm.

Another difference: A phantasm, being a sensible image, becomes very *vague and indistinct with complexity and minuteness of details*. We can readily form a phantasm of five trees in a row. But to imagine fifty (not forty-nine or fifty-one) trees in a row will be for most people an impossible task. To imagine five thousand (not more or less) trees in a row is an utter impossibility. But my idea of five thousand or five million trees is just as clear to my intellect as five or ten; I have no more difficulty in *understanding* the number 5,000,000 trees than I have in understanding the number 4,999,999 or 5,000,001. Similarly, in geometry a 'line' is conceived as having length but -no width; in other words, a line has dimension in one direction only. While this idea of a line is perfectly clear to my intellect, the phantasm or sense-image of a line will always be cast in two dimensions — length and width. Again, a geometrical 'point' is 'a limit terminating a line' or 'that which has position but no magnitude'; a 'point,' therefore, as considered in geometry, has position, but it has neither length nor width nor depth. However, just as little as any draftsman can make a point without giving it magnitude (for he will always make it something like a 'period' at the end of a printed sentence), just as little can the phantasm picture it without magnitude. But the intellect finds no difficulty in formulating the idea of a mathematical 'point,' as we see by the very fact of its definition.

Finally, there are many things of which we have a very clear *idea*, but of which *no reasonable phantasm can be formed*. Everybody speaks of such things as economics, law, virtue, soul, life, God, will, knowledge, ignorance, error,

inference, conclusion, logic, hypothesis, assumption, certainty, and a thousand similar things. Since we think and talk and argue about them, we surely have ideas of these things, but what imaginable phantasms can we make of such unimaginable realities? Or, can we invest the 'consistency' of an argument with anything like shape, weight, sound, size, color, or similar things that make up a phantasm? We do not even attempt to form a concrete sense-image of them; the words simply stand for the definite intellectual idea of these supra-sensible things, and so we content ourselves with thinking and speaking of them without forming a phantasm.

There is, therefore, a marked difference between the phantasm of the imagination and the idea of the intellect. The phantasm is always the concrete and sensible image of a concrete and sensible object, while the idea is the immaterial and supra-sensible representation of a thing, even when the thing itself is by nature concrete and sensible. Of course, since the intellect forms its ideas after a contemplation of the phantasm, it stands to reason that phantasm and idea, imagination and intellect, act in close harmony. Usually, therefore, a phantasm accompanies the idea; thus, the idea of 'man' will, as a rule, carry along with it the general image of a man. When it is impossible to form a real image of the thing represented in an idea (for instance, 'rationality, law, thought, mind, will, certainty,' etc.), the idea is accompanied by some word that designates it, as when we express the idea of the 'life principle' by the letters 's-o-u-l.' This is due to the fact that the intellect is dependent on the imagination to furnish it materials for

ideas; and this is also the reason why many people and even philosophers confuse the ideas of the intellect with the phantasms of the imagination. However, as has been shown, ideas are totally distinct from phantasms and should never be confused with them.

Logic, naturally, treats of ideas, not phantasms. Having established the fact that the idea is the intellectual representation of a thing in the mind, we must now study the elements -which constitute an idea.

COMPREHENSION AND EXTENSION

This brings us to a consideration of the *comprehension* and *extension* of the idea; they are its logical qualities. These qualities are of paramount importance in gauging the exact value of judgments and inferences and must, therefore, be thoroughly understood, if the mind would proceed accurately and safely in the attainment of truth.

By the *comprehension* of an idea we understand its meaning, signification, thought-content; and we define the comprehension of an idea as the *sum total of all the attributes or thought-elements which constitute the idea in its representation of a thing*. Take, for example, the idea of 'man.' What attributes or elements does it contain? Man is a 'being which is substantial, bodily, living, sentient, rational,' and these various attributes or elements form the comprehension of the idea of 'man.' If we desire to designate a particular individual called 'Franklin Roosevelt,' we will have to add to the comprehension of 'man in general' all those individual characteristics which

distinguish him from every other person. To give another example: The comprehension of the idea of an 'equilateral triangle' is 'a plane, rectilinear figure with three equal sides.'

While the comprehension gives the content of an idea, the *extension* expresses the *application* of this content to the individuals and groups in which it is found. The *extension* of an idea is therefore defined as the *sum total of all the individuals and groups to which an idea can be applied*. In the case of the idea of 'man,' its extension will include each and every individual in whom this idea of 'man' is realized, and that means every human being from the dawn of creation through the centuries until the crack of doom, whether he be a cave-dwelling Neanderthaler, an Australian native, or a highly cultured Parisian, or the future superman who will sail to Mars. Thus, too, the extension of the idea of 'plant' will embrace everything that is a vegetant non-sentient being, whether on land or in the sea or in the air, ranging all the way from the bacteria to the giant sequoias of California. The same, of course, is true of any other idea, like 'dog, cow, rose, orange, star, stone, hand, being, mind, house, blacksmith, boy, paper, book, rifle,' and so forth.

It will be well to bear in mind that the beings represented by an idea need have no actual existence, but only an existence in thought or fancy. Fairies, dragons, witches, ghosts are such; since, however, we have ideas of them, all the different fairies, dragons, witches, and ghosts ever thought of or described form the extension of these ideas. Again, certain ideas may have an extension which

does not include a number of individuals, but only a single one; 'the largest building,' 'the present heavyweight champion,' 'the tallest mountain,' 'the oldest man,' 'the last dinosaur,' 'the first bird,' 'the lowest valley,' 'the rarest coin,' and similar ideas, can have no more than a single member in their extension. Language and custom must also be considered. People frequently use expressions which ought to signify an entire class, but in reality they mean to include only a *limited portion* of the extension in their statement. Thus, when somebody says 'The Jew is a great business man,' he evidently does not intend to convey the idea that each and every Jew is a great business man, but merely a large portion of the Jewish race possesses this accomplishment. The use of language in this fashion is legitimate enough, provided the limitation of this extension is strictly adhered to in the course of an argumentation; to vary the meaning would give rise to confusion of thought and error in judgment. This conventional limitation of the natural extension of an idea is called the *universe of discourse*. It is obvious that this 'universe of discourse' has no value for logic, since the limitation of the extension is arbitrary and as such not subject to any definite law.

The terms *comprehension* and *extension* have received different names by numerous modern philosophers. For *comprehension* we find such terms as *implication*, *connotation*, *intent*, *intension*, while *extension* is expressed by such terms as *denotation*, *application*. The meaning, of course, is the same.

What is the *relation between the comprehension and the extension of an idea?*

It is usually stated that the comprehension can be neither increased nor diminished without changing the idea itself. This is perfectly true when we speak of *class-ideas* whose comprehension is definitely clear and fixed. In such cases the comprehension contains the essential elements of the class, and to take away an essential element would certainly change the whole idea of the thing. 'Man' (to quote again a favorite example) is a 'being that is substantial, bodily, living, sentient, and rational'; each of these elements is essential to the nature of man and cannot be omitted from his comprehension without changing the idea of 'man.' We also know that an 'animal' is a 'being that is substantial, bodily, living, and sentient'; here, too, we cannot change any of these essential elements without destroying the idea of 'animal.' For the longest time the comprehension of 'whale' was considered to contain the attribute 'fish' as an essential element, but science has proved that the whale is a true mammal, and thus the comprehension of 'whale' has been changed without destroying the idea of 'whale.' The reason for this is the fact that the farther we go from the broad classes in nature and the closer we come to the individuals, the more difficulty we find in discovering the really essential attributes which distinguish one from the other; in most cases of this kind we must be satisfied with a description of the nonessential elements of a thing in order to formulate its comprehension, even though it may not be entirely exact. In a general sense, though, the rule holds good that the comprehension can neither be diminished nor increased.

Logicians have a similar rule for the *extension* of an idea: It *can be diminished or increased* without destroying the idea. By this we mean that the comprehension of an idea can be applied to more or fewer individuals without any change in the idea as such. Thus, the idea of 'man' will remain the same, whether it is applied to one or to a billion individuals. Men are born and men die, but the idea of 'man,' considered in the comprehension as a 'rational animal,' remains ever the same. Trees may grow and multiply indefinitely, but the comprehension of 'tree' does not change on that account. Flowers bloom in the spring and summer and autumn in innumerable quantities and then die in the winter, but that fact does not alter the comprehension of the idea of a 'flower' in the least.

Hence the general truth of the rule: *The comprehension of an idea always remains the same, while the extension of the idea may change continually.*

There is another relation between the comprehension and extension of an idea which contains a general truth: As the *comprehension increases, the extension decreases*; and as the extension increases, the comprehension decreases. In order to illustrate the rule, let us take a progressive series of class-ideas. We shall start with the idea of 'living, bodily substance.' The comprehension of this idea has three elements, 'substance,' 'bodily,' and 'living'; its extension comprises all plants, brutes, and men. By adding the element 'sentient' to 'living, bodily substance,' so that we now have a 'sentient, living, bodily substance,' we have increased the comprehension, but we have also narrowed the extension, because we must now exclude the plants

from this extension, since they are not 'sentient'; the extension now comprises only the brutes and men. By adding the element 'rational' to 'living, sentient, bodily substance,' we have again increased the comprehension, but we have narrowed still more the extension, because we must exclude both the plants and brutes from this extension, leaving only man. By adding, for instance, the element 'Englishman' to the above-mentioned elements, we have again increased the comprehension, but we have also narrowed the extension down to the citizens of a single country. And if we add the element 'Londoner' to the element 'Englishman,' we have increased the comprehension to a still greater degree and have narrowed the extension down to the six millions of people who live in the city of London. The original three elements forming the comprehension of a 'living, bodily substance' has grown to be 'a man (i.e., a bodily, living, sentient, rational substance) who is a citizen of England and an inhabitant of London'; on the other hand, the original extension, which included the billions times billions of plants, brutes, and men, has decreased until at last it can be applied only to a comparatively small number of human beings. By reversing this process we shall notice that the comprehension will decrease in elements as the extension increases in numbers.

We must remember, however, that there is *no strict arithmetical proportion* in this inverse ratio between comprehension and extension. That would be a wrong application of the rule. Not every increase of attributes in the comprehension will always diminish the extension. True,

when I add 'English' to the comprehension of 'man,' I limit the extension of 'man' to the citizens of England; but when I add the attribute 'red-blooded' to 'man' (a 'red-blooded man'), the extension remains the same, since all men are red-blooded. Even in cases where the inverse ratio does apply, the result is very unequal and not always in a strictly arithmetical proportion; for instance, if we say 'white men,' the extension will include a far greater number of individuals than if I say 'crippled men.' Though not a hard-and-fast rule, therefore, in a general way the rule is fundamentally true and stands as stated.

Having considered the nature of the idea, the difference between phantasm and idea, and the logical qualities of comprehension and extension, we must now turn our attention to the various kinds of ideas.

SUMMARY OF CHAPTER I

1. The process of forming ideas reveals the *nature of the idea*. First in order is the phantasm. By means of abstraction the intellect extracts an intellectual image (idea) from out of the phantasm by leaving aside all the differentiating characteristics of the individuals and retaining the attributes common to them all. The idea, therefore, is the *intellectual image or representation of a thing*.

2. There is an essential *difference between phantasm and idea*. The phantasm is fundamentally concrete and individual and cannot be applied to a large number of individuals or to classes, while the idea is universal and applies with equal facility to any number of individuals taken singly or collectively. The phantasm becomes vague and indistinct with complexity and minuteness of details, while the idea is not interfered with by these things in its clearness and distinctness. No adequate 'phantasm can be made of a large number of things, though the idea of them is very definite and exact.

3. The *comprehension* of an idea is the *sum total of all the attributes or thought-elements which constitute the idea*. The *extension* is the *sum total of all the individuals and groups to which an idea can be applied*. The comprehension can be neither increased nor diminished without changing the idea itself, but the extension can be increased or diminished without changing the idea. Comprehension and extension have an inverse ratio or

proportion: as the comprehension increases, the extension decreases; and as the extension increases, the comprehension decreases.

Chapter 2

KINDS OF IDEAS

IDEAS CAN BE APPROACHED FROM DIFFERENT ANGLES AND DIVIDED in different ways. The philosopher will naturally attempt to procure a comprehensive division of the idea into its various kinds, because a complete knowledge of the idea in its manifold forms will tend to avoid confusion in discussions by fixing the meaning of the terms employed in all the departments of philosophy. Just as a thorough knowledge of the organs composing the human body enables the physiologist to understand the functioning of the human organism, so a fuller appreciation of the types of ideas will assist the philosopher in understanding the workings of the intellect in the pursuit of truth.

IDEAS ACCORDING TO ORIGIN

Ideas from the standpoint of their *origin*: intuitive and abstractive. Intuitive (or immediate) ideas are those which are formed as the result of the *direct perception of things*. As I stroll along the street, I see the blue sky, the sun, homes, stores, automobiles, people; I hear the purr of motors, the shrill laughter of children, the earnest

conversation of men and women, the weird shriek of a police siren; I feel the moist and frosty air of late autumn beating against my face; I smell the acrid odor of burned gasoline and the delicious fragrance of Antonio's fruit shop; I taste the sharp tang of the mentholated lozenge I am munching. All these and a thousand other things make their impression upon my senses; my senses convey their message to my mind; and my intellect forms the ideas of these things as I perceive them. At the same time I turn my attention to the mind itself and watch it form ideas of these things as they pass in review before it; in this way my intellect also forms ideas of my mind and its workings, because it perceives directly its own functioning. Two great worlds are therefore perceived by the intellect — the physical world around us and the world of thought within us. All ideas thus formed of *immediately present* objects, perceived as present, are intuitive.

Ideas are *abstractive* (or mediate), when formed *of objects by some means other than their immediate perception*. All my ideas of persons, things, and events which I acquire not by personal experience but through books, newspapers, or conversation with others, are of this type. Thus, too, from my knowledge of the regular succession of the seasons I have an idea of the coming summer, although summer is still many months away. From the effects of heat, light, and power I conclude to the existence of electricity as their cause, and I, therefore, have an idea of electricity, even though I cannot perceive electricity itself. From the universe at large I arrive at an idea of a Supreme Being, without being able to see this

Being directly by either the senses or the mind. Anything, therefore, of which I obtain an idea through deduction, through a process of reasoning, through the knowledge of some other thing, belongs to this class; such ideas are abstractive. It should be noted carefully that we are speaking of abstractive, not abstract, ideas; the two are very different, as will be seen.

IDEAS ACCORDING TO REPRESENTATION

Ideas from the standpoint of their *perfection in representing an object*.

Ideas may be clear or obscure. An idea is clear when it represents an object in such a way that it can be distinguished from any other object; otherwise it is obscure. Our ideas of the ordinary things of life in our everyday environment are clear. There is no obscurity in our ideas of a dog, an automobile, a clock, a book, a hand, a teacher, and a million other things; we can distinguish the idea of these things clearly among themselves. Many persons, though, will not be able to distinguish clearly between an African and an Indian elephant, between a mastiff and a St. Bernard dog, between a hesperornis and an archacopteryx, between a parallax and a parallelogram, between a thymus and a thyroid, and many other things: their ideas are obscure.

Clear ideas, again, will be either distinct or confused. They are distinct when they enable the intellect not only to distinguish the represented object from other objects, but also to enumerate the various attributes which make up the

comprehension of the object. Everybody, for instance, knows the difference between man and brute, but not everybody is capable of enumerating the thought-elements (attributed) which constitute the idea of 'man' and 'brute.' When I know that 'man is a bodily, living, sentient, rational substance' and 'brute is a bodily, living, sentient, non-rational substance,' I am enumerating the various elements (attributes) that constitute the comprehension of their idea, and my idea is therefore distinct; if I cannot make this enumeration, my idea is *confused*.

Clear and distinct ideas are either adequate or inadequate. They are *adequate* (complete) when the intellect can enumerate *all* the attributes belonging to the comprehension of a thing, even to the last and least. My enumeration of the attributes of 'man,' given in the foregoing paragraph, is adequate; were I to omit one, for instance the attribute 'sentient,' but retain the differentiating mark 'rational,' then my idea of 'man' would be clear and distinct, but *inadequate* (incomplete). Thus, too, I may have a clear and distinct idea of gold, silver, iron, and other metals, considered from the viewpoint of their physical qualities; unless, however, I can also enumerate their chemical qualities, my idea of them would be inadequate (incomplete).

It will be readily seen that the different types of ideas mentioned above are subjective in character, depending on the individual persons and their knowledge or ignorance of things: the ideas will change from obscure to clear, from confused to distinct, and from inadequate to adequate, as their knowledge of things becomes more and more perfect.

IDEAS ACCORDING TO THEIR RELATIONS

Ideas from the standpoint of their *mutual relations*.

Ideas are either connex or disparate. They are *connex*, when one idea necessarily either includes or excludes the other. Ideas like 'father — child,' 'husband — wife,' 'teacher — pupil,' 'man — rational,' 'superior — inferior,' include each other; while ideas like 'light — darkness,' 'day — night,' 'vice — virtue,' 'rich — poor,' exclude each other. Ideas are *disparate*, when they neither necessarily include nor necessarily exclude each other. Such ideas are 'man — black,' 'wise — good,' 'gold — warm,' 'iron — wheel.' A wheel may consist of iron, but it need not. A man may be black, but some men are not.

Again, ideas are either identical or diverse. They are *identical* when their comprehension is the same, as 'man — rational animal,' 'water — H₂O,' 'chloride of sodium — salt,' 'plant — non-sentient organic substance.' They are *diverse*, when their comprehension is different, as 'man — brute,' 'silver — diamond,' 'tree — dog,' 'house — automobile.'

Diverse ideas will be either compatible or incompatible. They are compatible, when the attributes of the comprehension of both can be united into another (third) idea; thus the ideas of 'man' and 'white' ('white man'), 'vegetant' and 'sentient' ('brute'), 'wise' and 'good' (a 'good, wise' man) are compatible. But if the comprehension of the one idea excludes the attributes of the other, these ideas are incompatible; such are 'wisdom — folly,' 'vice — virtue,' 'red — blue,' 'light — darkness,' 'iron — wood.'

The *repugnance of ideas*, which forms the basis for their in-compatibility, may be of different kinds. This gives rise to contradictory, privative, contrary, and relative ideas.

Contradictory ideas are those, of which the one simply denies the comprehension of the other, as 'organic — inorganic,' 'thing — nothing,' 'metallic — nonmetallic,' 'equal — unequal,' 'good — not good.' Contradictories are so mutually exclusive that the one cannot apply if the other does, and the one must apply if the other does not; there is no middle ground left, if both are excluded. Thus, any object must be either organic or inorganic; and if both ideas are removed, there is nothing left.

Privative ideas are those, one of which signifies a perfection and the other denies a perfection in a subject which naturally ought to possess it. 'Sight — blindness,' 'living — dead,' 'sanity — insanity,' 'sound — lame,' 'healthy — diseased,' are such. If the subject has no natural aptitude to possess the perfection, then the absence of this perfection will not constitute a 'privation,' and neither of the two privatives will apply. A stone, for instance, is not supposed to have life, and therefore a stone, not having life, cannot be said to be dead, but merely 'lifeless'; while a plant is supposed to live, and therefore a plant, if it has ceased to live, is 'dead.' Similarly, men are 'blind,' if they cannot see, because they have the natural aptitude to see; but plants are not 'blind,' but merely 'sightless,' because they are not supposed to see. In other words, in things which possess the same natural aptitude for a perfection, privative ideas are mutually repugnant and exclusive, but not when applied to things devoid of such a natural

aptitude; there is a middle ground here, 'sight — *sightless* — blind,' 'life — *lifeless* — dead.'

Contrary ideas represent the two extremes among objects of a series belonging to the same class. Such are 'white — black' in the line of color; 'kind — cruel,' 'wise — foolish,' 'prodigal — avaricious' in the line of conduct; 'pleasant — painful,' 'happy — miserable' in the line of emotion; 'king — slave' in the line of social standing; 'hot — cold' in the line of warmth. Contraries are mutually exclusive; they cannot be true at the same time in the same subject. But between contraries there is always a middle ground, and therefore both contraries may be false at the same time. No object, for example, can be 'white' and 'black' at the same time (contraries are mutually exclusive); it might be, though, neither white nor black, but blue or red or green (contraries may be false together). So, too, if a man is avaricious, he cannot be 'prodigal,' and vice versa; but a man may be 'thrifty' or a 'normal spender,' and in that case he is neither prodigal nor avaricious. Contraries always presuppose a series, consisting of extremes and intermediate stages leading from the one extreme to the other.

Relative ideas are two incompatible ideas united in such a way that the one cannot be understood without the other. Such are 'father — child,' 'master — servant,' 'cause — effect,' 'east — west,' 'left — right,' and so on. We must bear in mind here, that the identity of relationship must be retained throughout. In the relatives 'father — child' we consider merely the relationship existing between these two, and the two ideas are mutually incompatible and

exclusive: if one is the 'father,' he is not the 'child,' and vice versa. Of course, a man who is a 'father' to his own child, will be a 'child' to his own father; but then we have a second relationship, different from the first.

A little consideration of contradictory, privative, contrary, and relative ideas, as explained above, will show that they are valuable: if I am certain of the truth of a statement containing one incompatible idea, I am equally certain of the falsity of the opposite statement. Consider this statement: 'The mimosa is a plant.' Since a plant is a 'non-sentient organism,' I can immediately conclude that the mimosa has no nerves, even though the collapse of its leaves at a mere touch would suggest that it has feeling; a mimosa is therefore no animal.

IDEAS ACCORDING TO COMPREHENSION

Ideas from the standpoint of their *comprehension* or thought-contents.

They are *simple* ideas, when their comprehension consists of one single attribute or element; if the comprehension consists of more than one, they are *composite*. 'Being,' 'thing,' 'one,' are therefore simple ideas, because their comprehension comprises but a single attribute or element. Practically all other ideas are composite, like 'man,' 'plant,' 'animal,' 'metal,' 'child,' 'butcher,' 'baker,' 'millionaire,' 'house,' etc., because their comprehension is composed of a number of attributes or elements; thus, the idea of 'man' consists of 'substance, body, living, sentient, and rational'

Then, too, we distinguish between concrete and abstract ideas. Ideas are concrete, when they express a nature or determining attribute as inherent in a subject; but when ideas express a nature or determining attribute considered (by the mind) as separated from the subject in which it inheres, they are abstract. A concrete idea always represents a thing (nature or attribute) as it is found in reality. Such is the idea of 'man,' 'rose,' 'house,' 'horse,' 'cow,' 'animal,' 'substance,' etc., representing the natures of things; or the idea of 'white,' 'small,' 'wide,' 'ebullient,' 'high,' 'blue,' 'dull,' 'sharp,' etc., representing the attributes of things. These same realities become abstract, when I consider them independently and alone for themselves. For instance, a 'man' is always an individual thing, and therefore concrete; but 'humanity' is an abstraction, considering man's nature for itself alone and independent of any individual, and therefore abstract. 'Substance' is also concrete, but 'substantiality' is abstract; 'animal' is concrete, but 'animality' is abstract. So, also, 'white,' 'small,' 'wide,' etc., are concrete; but 'whiteness,' 'smallness,' 'width,' 'ebullition,' 'height,' 'blueness,' 'dullness,' 'sharpness,' etc., take the same attribute, leave aside the subject in which they inhere, and consider them (in the mind) as if they had no subject, and thereby they become abstract ideas. The difference between the two kinds of ideas will be readily observed in the following statements: 'Some roses are red,' and 'Redness is a quality of color in some roses.'

IDEAS ACCORDING TO EXTENSION

Ideas from the standpoint of their *extension*. Viewed from this standpoint, ideas may be singular, universal, particular, or collective.

Ideas are *singular*, when they represent a *single object* only. Such ideas will be expressed either by proper names like 'George Washington,' 'Cicero,' 'Napoleon,' 'Bobby Jones,' 'Jack Dempsey,' 'Knute Rockne,' etc., or by means of class names restricted in such a manner that they can apply to only one thing, as 'this pen,' 'that man,' 'the present king of Italy,' 'the man over there with the derby and black overcoat,' and the like. The following Latin distich gives the *individuating notes*, or characteristics distinguishing one individual from another.

Farina, figura, locus, tempus, stirps, patria, nomen.
Haec ea sunt septem quae non habet unus et alter.

'Forma' — any *quality* of a thing, like 'black,' 'virtuous,' 'vivacious,' 'slow.' 'Figura' — *disposition* of parts or members, like 'tall,' 'stooping,' 'well-proportioned,' 'hunch-backed,' 'abnormal.' 'Locus' — place, like habitation, birthplace, localities visited in travel. 'Tempus' — *time*, like age, date of birth, dates of events in life. 'Stirps' — *ancestry*, like parents and relatives. 'Patria' — *country*, like citizenship. 'Nomen' — name, like 'Franklin D. Roosevelt,' 'Charles the Great,' 'Pope Pius XI.' While it is true that some individuals may have a number of such characteristics in common, it is obvious that no two individuals can have them

all alike. Ideas are *universal*, when they represent some common nature or attribute which can be applied to a *class as a whole* and to *each individual* of that class. 'Man,' 'plant,' 'dog,' 'soldier,' 'city,' 'hat,' and the great majority of ordinary ideas are of this kind. The comprehension of such an idea fits each and all. The idea of 'man,' for instance, in the sentence 'Man is a rational animal,' applies as well to each individual man as it does to all men taken together as a class. The statement 'The cat is an animal' is as true of the puss in my house as it is of all the cats that have ever lived or will ever live. Strictly speaking, it is not necessary that the idea apply to a number of actual individuals in order to be a universal; it will be sufficient if the idea is such that it is capable of being applied to a number of individuals (actual or possible) as a class, even if at the moment there be only a single individual in existence. Thus, even when the first human being alone existed, the idea of 'man as a rational animal' had the same universal application as now when there are two billions of humans on the globe, because these individuals were possible at the time and as such could be united into a class by the mind. All that is necessary is that the idea represent some common element present in one individual which will also have to be present in every other individual of that class, provided other individuals have at least the possibility of existence.

Particular ideas are *universals taken partly and indeterminately*. While the singular idea applies to only one individual and the universal idea applies to each and all of a class, the particular idea applies neither to one nor to all, but to some of the class in an indeterminate manner. If we

can place the word 'all' or 'every' before an idea ('man — all men'), it is universal; but if we place the word 'some' or its equivalent before an idea, it is particular. 'Man is mortal' is the same as 'All men are mortal,' and here 'man' is a universal; but if we say 'Some men are white,' we restrict the universal idea 'man' to an indeterminate portion of the whole class and we then have a particular idea. In judging whether an idea is taken in a universal or in a particular sense, we must often consider the usage of language. In a statement like 'Englishmen have no sense of humor,' no one intends to assert that 'All Englishmen have no sense of humor,' but merely that a 'large portion of Englishmen' lack this quality. The context of the book or conversation will usually indicate whether the idea is to be taken as a universal or as a particular idea.

The *collective* idea is one that applies to all the *individuals as a class, but not to the single members of the class*. 'Army,' society,' 'library,' 'Church' (the organization, not the building), 'herd,' 'flock,' 'galaxy,' 'squad,' 'company,' etc., are such. 'Army,' for instance, can be applied to all the soldiers taken together as a class, but it cannot be applied to the soldiers taken singly and individually, for no one can call the single soldier an 'army.' A number of cows form a 'herd,' but the individual cow is not a herd.' Of course, when we take a number of armies and consider them as a class or group, then the idea 'army' will be a universal. Thus, when we state that 'An army is an offensive and defensive weapon of the State,' we apply the idea 'army'. to all armies, and then the idea of 'army' is a true universal, because it applies to each and every army (German,

French, English, American, etc.). But when we speak of a single 'army,' it is a collective idea, even though a number of individual soldiers comprise it, because the idea 'army' cannot be applied to the individuals who constitute the group. Again, consider the statement that 'A library is a collection of books.' The idea 'book' is a universal, because the idea applies to each and every book in the library; but the idea 'library' is collective, because it can only be used of all the books taken together and does not apply to the single volumes as such.

Singular, universal, particular, and collective ideas play an important part in argumentations, and their significance should be clearly grasped. And among them the universals are of prime importance; they will therefore receive special consideration in the following chapter.

SUMMARY OF CHAPTER II

There are *different kinds* of ideas:

1. From the standpoint of their *origin*: intuitive and abstractive.

2. From the standpoint of their *perfection in representing an object*: clear or obscure; distinct or confused; adequate or inadequate.

3. From the standpoint of their mutual relations: connex, or disparate; identical or diverse; compatible or incompatible; contradictory, privative, contrary, relative.

4. From the standpoint of their *comprehension*: simple or composite; concrete or abstract.

5. From the standpoint of their *extension*: singular, universal, particular, collective.

Chapter 3

UNIVERSALS

THE PROBLEM OF THE UNIVERSAL IDEA IS OF THE GREATEST importance for philosophy and science. The universals lie at the very foundation of scientific knowledge.

It is the purpose of all science to sift the data of phenomena, analyze the manifold occurrences of the world, and extract from their ever-changing realities that which is permanent and necessary, formulating classifications and laws whose constancy is recognized as valid for all times and all places. These laws must apply to each and every occurrence, and the single occurrences are nothing but the individual manifestations of the general law in operation. Thus, the law of gravitation states that 'Every portion of matter in the universe attracts every other portion, and the stress between them is directly proportional to the product of their masses and inversely proportional to the square of the distance between their centers of mass? Another law, the law of biologic origin, states that 'Every living being derives its origin from another living being, every cell from another cell, every nucleus from another nucleus, and every chromosome from another chromosome.' Laws such as these apply not only to this or that body, here and there,

now and then; *they are valid for all bodies, everywhere and always*. If this were not so, our entire knowledge of the universe would be individualistic and relative, and all science would then collapse. But the very fact of the validity of these classifications and laws presupposes that the nature of the bodies in a class are the same, *with the sameness of a perfect likeness*, so that their actions will also be the same in all places and at all times. The constancy and sameness of these natures amid all individual differences is therefore the reason for the validity of these classifications and laws; and it is also the reason why these natures can be expressed by a universal idea applicable to all and to each single one of a class, because the universal idea represents the *class-nature*. Science, therefore, in the formulation of its classifications and laws, uses universal ideas throughout, and the validity of science (and of philosophy, the super-science) stands and falls with the validity of the universals. This shows us the vital importance of the doctrine of the universals.

NATURE OF THE UNIVERSALS

We must, of course, uphold the validity of science and, in consequence of this, also the validity of the universals; otherwise all our knowledge will end in skepticism. This seems obvious. But the matter is not quite so simple. The universals present a real problem to the scientific philosopher and the philosophic scientist. Since all ideas 'are representations of things as they are in themselves, *universal* ideas must also represent things as they are in

themselves. And right here we have the main difficulty and the crux of the problem.

A universal idea is one whose thought-content (comprehension) applies to a class as a whole and to each and every member of that class. Take the idea 'man' as a 'bodily, living, sentient, rational substance? This idea applies in the same way to each 'man' taken singly and to 'all men' taken together as a class. Now, if the universal idea 'man' is a true representation of man as he is in reality, then this would seem to imply that 'man; as found in reality, has a nature which is single in each individual and one in the whole class. The nature of man would be *one*, because it applies to the class as a whole; and it would be *multiple*, because it applies to each individual of the class. How can it be *one and multiple* at the same time? This seems a patent contradiction, and a contradiction would invalidate the universal idea as a true representation of things. But if this is the case, what value is there in science and in philosophy, since they are based entirely on universals?

The difficulty, however, is more apparent than real. A closer examination of the universals will explain and remove the seeming contradiction. At the same time it will place the universals, and with them science and philosophy, upon a more solid foundation.

The world about us consists of single things, of *individual natures*. There are, for instance, two billion men, each of whom possesses his own individual nature; and each nature possesses a great number of characteristics, consisting of differences in color, weight, size, bodily formation, mental and emotional peculiarities, etc., distinguishing one person

from another. In other words, no two human beings are alike in every respect. It is in this way that our senses perceive individual men; and the phantasm derived from these sense-perceptions represents these individuals with all their concrete characteristics and differences. The intellect, however, in viewing and examining this phantasm, soon realizes that there is something *permanent and common* to all these individuals, notwithstanding the many differences. It perceives that some of these characteristics are always present in each and every one of these individuals and make it to be what it is; these characteristics constitute the *nature or essence* of the individual, without which it cannot exist and without which it *cannot remain what it is*. The other characteristics are such that they may be missing in some individuals, or at least they are clearly recognized to be such that the *nature or essence would remain the same without them*. In the example of 'man,' the intellect perceives that the elements of 'a bodily, living, sentient, rational substance' are found in each individual at all times, and these elements are such that a man would cease to be a 'man,' if any one of them were missing; they therefore constitute the nature or essence of 'man as such, and this nature or essence is common to each and all. The intellect also perceives that all other characteristics, like weight, color, size, bodily formation, mental and emotional peculiarities, etc., are such that they either are or may be absent in some or all individuals, without a man ceasing to be a 'man, i.e., without changing his nature or essence.

Here, then, we have the basis for the origin and validity of universal ideas. From the phantasm, representing the individuals in all their concrete characteristics and differences, the intellect *abstracts* or draws forth the *nature or essence common to all the individuals of a class*, leaving aside the nonessential characteristics which distinguish one from another. This nature or essence is, of course, a *reality*, and is *actually present* in the individuals, independent of our intellect. The intellect now includes this nature or essence in a single idea, and this idea is therefore a true representation of this nature or essence. And since this nature or essence (for instance, 'man' as a 'bodily, living, sentient, rational substance') is recognized by the intellect as being the same with the *sameness of a perfect likeness* in each individual taken singly and in all individuals taken as a class, the comprehension of the idea of 'man' will apply to the class as a whole and to each individual as a member of the class. And that is what we mean by a universal idea. The *universal* is therefore a *true representation* of things as they are in themselves, even though it leaves out of consideration all the differentiating characteristics which accompany this nature or essence in reality. The Chinaman and the Zulu, the Mohawk and the Inca, the Egyptian and the Greek, the Hawaiian and the Eskimo, the Jew and the Slav, the European and the American — all, individually and collectively, possess the same (not identical, but like) common nature or essence. The idea of this common nature or essence then also applies to all, individually and collectively, and is therefore a true universal.

As will be noted from the above, there is *no actually universal nature or essence in the things themselves*, in the sense as if there were one universal nature, for instance of 'man,' and the single individuals would all together share in this one nature; each one possesses his own nature, distinct from that of his fellow men. The universality of the universal idea is thus a *product of the mind*, in virtue of its power to recognize the common nature in the various individuals of a class. The universal *as a universal*, therefore, exists only in the intellect, but its foundation lies in the common nature existing in the things themselves. This has been pithily expressed in the famous principle, *Universalia sunt formaliter in mente, fundamentaliter in rebus ipsis*, that is, 'universals are formally (actually, strictly speaking) in the mind, fundamentally in the things themselves.' Viewed this way, there is no contradiction in the doctrine of the universal. The universal is a true representation of reality and it safeguards the validity of scientific knowledge. Later on, in another department of philosophy, this problem of the universals will receive a fuller treatment, in connection with other cognate systems of thought and philosophy.

If we now summarize the various stages in the development of the universal idea, we find that the following process takes place in our acts. First, we perceive the single *individuals*; then, the *common nature* of these individuals is drawn forth by mental abstraction, leaving aside all the differentiating and individualizing characteristics, and this common nature is expressed by the intellect as a *universal* idea (direct universal); finally, this common nature is compared with all the individuals of the

class and examined as to how it is *present in all as individuals and as a class* (logical universal). This leads us to a consideration of the direct universal with its categories and of the logical universal with its predicables.

DIRECT UNIVERSALS: CATEGORIES

The direct universal is one which expresses the *nature or essence of a thing as the thing is in itself*, without relation to other things or ideas. It considers and manifests only the thought-content, the *comprehension*; the intellect, of course, perceives that it can be applied to one and many at the same time, but as yet it abstains from considering whether and *in what manner* it applies to the individuals and the class. Bearing this in mind, it will not be difficult to understand the various terms used by philosophers to designate this type of universal; it is variously styled as 'direct,' 'real,' 'immediate,' 'metaphysical universal,' a 'universal of the first intention.'

A few words will explain the reason for these various designations. It is called a 'direct' universal, because it expresses the nature of the object as it is found *directly and immediately* in the *real* order of things existing in the world around us. This also explains why it is called an 'immediate' and 'real' universal. It is termed 'metaphysical' universal, because the intellect penetrates '*beyond the physical*' properties of the object and abstracts the nature or essence without its differentiating characteristics. And since it is always the first act or 'intention' of the mind to represent *things as they are in themselves*, before comparing them

with others, the direct universal is also termed a universal of 'first intention.'

An example will show this more clearly. When I form the universal idea 'man' as a 'bodily, living, sentient, rational substance,' or simply as a 'rational animal,' I merely state the nature or essence of 'man' as it exists in the real order of things, independent of all comparison with other things or ideas. I do not consider here, for instance, whether 'rational animal' constitutes the whole or only a part of man's nature, nor whether 'rational animal' is the 'genus' or 'species' of man nor whether and how it can be applied to men as individuals and as a class; to do that would make the universal a *logical* universal, because then I am considering it as it exists or *an idea* in the conceptual order, rather than as the representation of 'man' in the real order of things.

Having explained and defined the direct universal, our next task will be to examine the different *types* of direct universals. Many sorts of divisions have been attempted and made by philosophers, but the most serviceable is still that of Aristotle who classified the direct universals into ten so-called categories or *predicaments*. As the word indicates (*κατηγορία*, predicate, from *κατηγορεῖν*, to predicate, affirm or deny), Aristotle intended the categories to be the supreme and ultimate classes of 'predicates' as found in our judgments and sentences; in as much, however, as these predicates are direct universals, the categories or predicaments are the supreme and ultimate classes of direct universals. *Categories or predicaments* are therefore *the supreme and ultimate classes of direct universals*.

Primarily, then, the categories are classifications of direct universal ideas, but since direct universals are representations of real beings, the categories are also the supreme and ultimate classes of *being* in which things are realized. In logic, of course, we are only concerned with the categories as classes of ideas, so as to establish order in our *knowledge*; but it is impossible to avoid reference to the *reality* of things represented by these universal ideas, because that is the only way in which we can test the value of the categories.

The Aristotelian categories, as has been stated, are ten in number. They are: *substance, quantity, quality, relation, action, passion, when, where, posture, habitus*. Each will be explained in turn.

Substance is a being existing in and for itself, needing no other as a subject in which to exist. Examples: man, lion, dog, tree, bush, house, stone, gold, iron. It is the answer to the question: 'Who or what is this thing?' 'The oak is a *plant*; iron is a *metal*.'

Quantity is a modification of the material (determinable) element in a being; extension, number. Examples: weight, size. It is an answer to the question: 'How much or how big?' 'The pole is *ten feet long*; it weighs *one hundred pounds*.'

Quality is a modification of the formal (determining) element in a being. Examples: intelligence, strength, health, warmth, color, faculties of body and mind, etc. It is an answer to the question: 'What sort of thing is it?' 'The rose is *red*'; 'the stove is *hot*'; 'man is *intelligent*.'

Relation is the reference or bearing of one being to another. Examples: paternity, equality, superiority, likeness. It is an answer to the question: 'To what or whom does it refer?' 'He is a father,' 'a teacher,' 'a president'; 'he is *older*,' 'younger,' 'heavier than—'; 'it is *similar*,' 'equal to—.'

Action is the production of an effect in another; it is expressed by the active, transitive verb. Examples: painting a picture, baking bread, shooting a deer, sawing a board, peeling a potato, driving a car. It is an answer to the question: 'What does it do?' 'The dog is *gnawing* a bone'; 'the boy is *throwing* a stone'; 'the man *broke* his arm.'

Passion (reaction) is the reception of an effect from another. The term is used in the sense of 'bearing, enduring, suffering, receiving, being acted on'; it is expressed by the passive voice of the transitive verb. Examples: being heated, being killed, being shoved, being lifted. It is the answer to the question: 'What is happening to it?' 'The anchor is *dropped*'; 'his hands are *burned*'; 'the flag is furled'; 'the man is shot.'

When is situation in time. Examples: today, tomorrow, yesterday, soon, ten years ago, in the beginning, sometime, in the future. It is the answer to the question: 'When,' 'at what point of time?' 'He was there *last year*'; 'the mail will arrive at 8 a.m.'; 'the ship is docking *now*.'

Where is position in space. Examples: upstairs, in the country, on the mountainside, below deck, in bed, on the table, in the bottle, at home. It is the answer to the question: 'Where is it?' 'He is *downtown*'; 'the book is *on the shelf*'; 'the car is *in the garage*.'

Posture is immanent or intransitive action expressed by an intransitive verb; disposition of parts among themselves, in the sense of 'attitude.' Examples: sitting, upright, standing, lying down, sideways. It is the answer to the question: 'In what attitude?' 'The tower is *leaning*'; 'the dog is *running*'; 'the boy is *lying down*.'

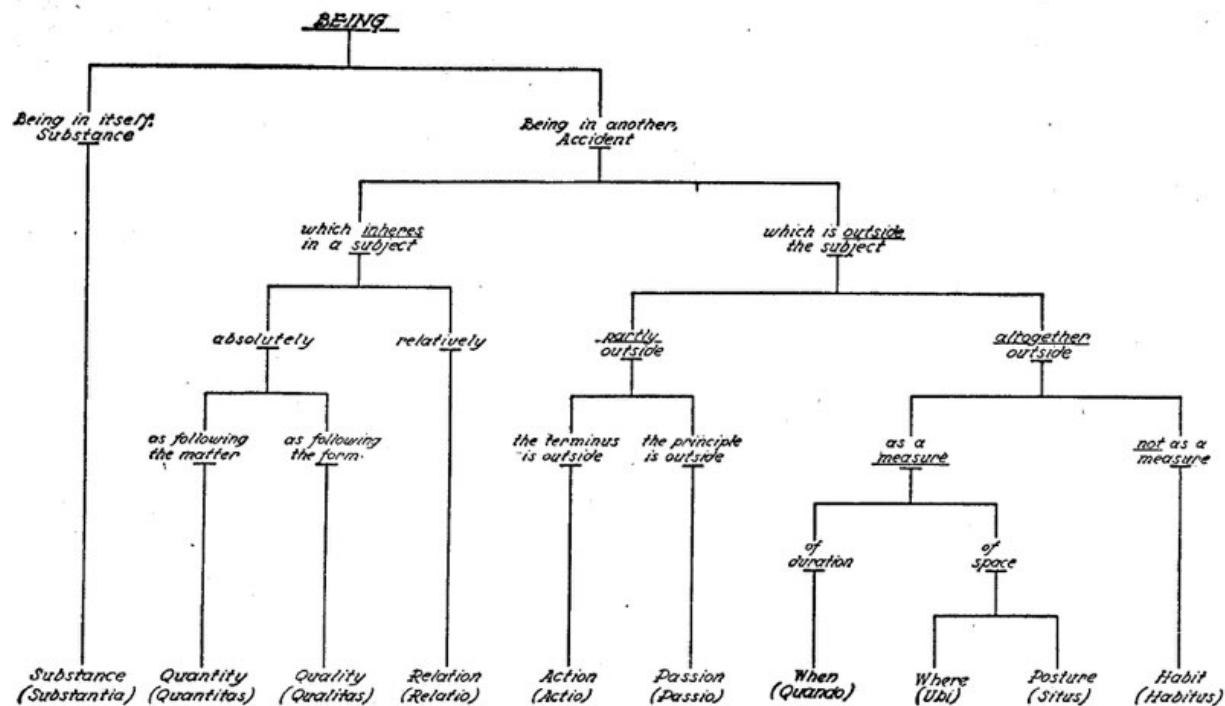

Habitus is clothing, equipment, physical adjuncts; or state, as expressed by the reflexive verb. Examples: clothed, shod, armed, hatted; praising one's self, hurting one's self, loving one's self. It is the answer to the question: 'How surrounded, equipped; how conditioned?' 'He *wears gloves*'; 'she has a red tam *on her head*'; 'he is *disgusted with himself*.'

THE QUESTION NATURALLY ARISES. WHY ARE THERE JUST TEN categories? Is there any special reason in the things themselves for this division? There is. This classification is not arbitrary, but fully grounded on the various kinds of being found in the real order. Thus, *everything either exists in itself or in another*. Now, something that exists in itself is called a substance; if it needs another, a subject, in which it must exist, it is called an accident.

We discover the nine kinds of accidents in the following manner. An accident determines and modifies the subject either *directly in its being or in reference to something outside of it*. In the first case, it modifies the subject either in its material element, and then we have *quantity* (size, weight); or in its formal element, and then we have *quality* (color, goodness, etc.). In the second case, the accident

modifies the subject by giving it a *reference* to something else, and then we have *relation* (similarity, professorship, fatherhood, etc.). The accidents enumerated so far have their source in the subject; other accidents, however, modify their subject in virtue of some reason *outside their subject*. Thus, some accidents modify their subject in virtue of some effect which the subject produces in another, and then we have *action* (heating something, cutting something, etc.); or in virtue of some effect which the *subject receives from another*, and then we have *passion* (being heated, being cut, etc.). Other accidents may modify their subject in virtue of the measurement of its *location*, and then we have *place* (upstairs, in the city, etc.); or in virtue of the measurement of its duration, and then we have *time* (last year, now, tomorrow, etc.); or in virtue of the determination of its attitude and the disposition of its parts, and then we have *posture* (top-heavy, singing, walking, etc.). Finally, some accidents may contribute a purely external modification to their subject by belonging to its *environment*, its *habiliments*, its *conditions*, and then we have *habitus* (clothes, weapons, being well pleased with one's self, etc.). Hence the ten categories.

The reason for the division of categories can also be exemplified by means of the following schematic illustration:

Some thinkers are convinced that they have a legitimate reason to quarrel with Aristotle regarding his list of categories. They claim that the categories are not mutually exclusive and irreducible. 'Action' and 'passion,' for example, are really only two phases or aspects of causality in as much as the change effected by the cause is produced by the one and received by the other. Still, there is a difference; because the subject producing, and the object receiving, the change, may be two different entities. These philosophers have more claim to truth when they assert that 'time' and 'place' and 'posture' are reducible to the more general category of 'quantity.' This is true enough, if we consider the categories as *modes of being*; but the categories are primarily intended as classifications of *ideas* rather than as modes of being, and people as a rule consider ideas of 'time' and 'place' and 'posture' sufficiently

distinct among themselves and in relation to 'quantity' in general to warrant their place in the list as separate categories of universals. As a matter of fact, all the categories, with the exception of 'substance,' are reducible to the general category of 'accident'; this, however, is of no practical use, since we would then be compelled to subdivide 'accident' into further divisions of 'quality,' 'quantity,' 'relation,' etc., giving us the same end- result which Aristotle attained by leaving the supreme class of 'accident' entirely aside. After all, then, Aristotle's division of the direct universals into ten ultimate categories must be considered the most serviceable in establishing order in our knowledge. The number is neither too large nor too small; and the compactness and complexity, the unity and flexibility of the list is such that it is eminently suitable for all practical purposes. No other list devised by philosophers the world over has ever been found to be better. Kant, the German philosopher, set up a list of twelve categories, based upon the classification of judgments according to their quantity, quality, relation, and modality. Since these 'categories' are a classification of *judgments* rather than of ideas, they do not deserve the name of 'categories' in the accepted sense and they will not receive any consideration in this connection. Their purpose in Kant's system is very different from those mentioned here.

Having discussed the direct universal and the categories or predicaments, we must now turn our attention to the logical universal and the predicables.

LOGICAL UNIVERSALS: PREDICABLES

The direct universal expresses the nature of an object in the real order, without considering how it applies to the individuals and the class; it considers merely the comprehension of the idea, in as much as it is a representation of the thing's nature. When, however, the intellect considers also the *extension* of the universal and reflects on the contents of an idea to see *how* it applies to its subjects *precisely as a universal*, namely whether as their complete essence or only as a part of their essence or otherwise, then the universal is taken as a logical universal. It is also styled a 'reflex' universal or a universal of 'second intention,' because the intellect, after forming the direct universal first ('first intention'), turns its attention to ('reflects on') the universal itself as a universal, in order to observe how it applies to one and many. A logical & reflex universal, therefore, is defined as a universal which expresses a nature common to many, *precisely insofar as it is applicable to many*.

An example will show the difference between a direct and a logical universal. When I say 'Peter is a rational animal,' the idea of 'rational animal' is a direct universal, because I am merely stating his nature as it is found in the real order. But when I take the same sentence and say that the predicate 'rational animal' expresses the *complete* essence of Peter's nature, I am comparing the direct universal 'rational animal' with the subject 'Peter' and state *how* this predicate applies to the subject. Thus, too, when I state 'Peter is an animal,' the idea of 'animal' is again a

direct universal. But when I consider the same sentence and state that the predicate 'animal' applies to the subject 'Peter' as only a part of his essence (because, besides being an 'animal,' he is also 'rational'), then again I state *how* the predicate is attributed to the subject. This brings us to the 'predicables.'

Predicables are the *different modes or ways in which a universal can be predicated of its subject*. Now, there are five such modes, five predicables. And there can be neither more nor less. The proof is simple enough. The universal used as the predicate will either express the essence (nature) of the subject, or it will not express the essence. If it expresses the essence, it will either express (1) the *whole* essence, or only a part of it. If only a part of the essence, then either (2) the part which it has in *common* with others or (3) the part which *differentiates* it from all others. But if it does not express the essence, then it expresses something superadded to the essence, and this *superadded* reality must be something either (4) necessarily connected with the essence or (5) merely *accidentally connected* with the essence. There are no further possibilities. The predicables are, therefore, five in number and they are called, in the order enumerated above, 'species,' 'genus,' 'differentia,' 'property,' and 'accident.' These will now be explained.

Species: it is a universal idea which *expresses the whose essence of its subject*. An example will make the meaning clear. In the sentence 'Man is a rational animal,' I am predicating the idea 'rational animal' of the subject 'man.' Upon comparison I find that 'rational animal'

expresses, not a part, but the *whole of 'man's' essence*, because we understand by 'mans precisely this that he is a 'rational animal.' Therefore, the idea 'rational animal' represents the 'species' of the idea 'man,' and this is true, whether I apply the idea 'rational animal' to all men together as a class or to the individual men (Peter, Paul, John, James, etc.) who fall under the class. In a similar way the idea 'irrational animal' is the species of all 'brutes' (insects, birds, fishes, mammals, etc.), because that expresses their complete essence. And when I state 'Plants are organized (living) bodies,' then the predicate of this sentence expresses the whole essence of 'plant' and is, therefore, its 'species.' In the same way 'inanimate body' is the 'species' for all metallic, nonmetallic, and metalloid substances like gold, silver, carbon., arsenic, etc. And 'immaterial substance' is the 'species' for the entire spirit world. In all such cases I express their complete, or *specific*, essence.

As a mere matter of precaution, it is well to note that 'species,' as used in logic here, must not be confused with 'species' as the term is used in the natural sciences; a 'species' in the sciences is a classification of animals and plants which are fertile among themselves. The meaning is totally different.

Genus: it is a universal idea which *expresses a part of the essence of its subject, that part which the subject has in common with other species in this same class*. In the sentence 'Man is an animal,' the predicate 'animal' expresses only a part of man's essence, namely that *part* which 'man' has in common with 'brutes.' 'Man' and 'brute'

are both 'animals,' i.e., 'bodily, living, sentient substances,' and as such, belong together as 'species' under the wider universal 'animal.' For the same reason 'plants' and 'animals' are species under the 'genus' of 'living bodies,' because the latter idea expresses the essence which both have in common; 'living bodies,' therefore, is the 'genus' of plants and animals. So, too, 'body' is the 'genus' for the two species of 'organic' and 'inorganic' beings beneath it; and 'substance' is the 'genus' for 'material' and 'immaterial' beings.

Differentia: it is a *universal idea which expresses a part of the essence of its subject, that part which distinguishes one species from another under the same genus.* 'Man' and 'brute,' for instance, are the two species under the same genus 'animal'; 'animality' is the part of the essence common to both. Now, what distinguishes or differentiates the 'animality' of 'man' from the 'animality' of the 'brute,' so that both belong to different species? It requires some *determining and differentiating* essential element to limit it to the 'species' of 'man' and 'brute.' This differentiating essential element is 'rationality' in man and 'irrationality' in the brute. 'Rationality,' added to 'animality,' constitutes the whole essence of 'man,' and this is his 'species' ('man is a rational animal'); 'irrationality,' added to 'animality,' constitutes the whole essence of 'brute,' and this is its 'species' (the 'brute is an irrational animal'). In a similar manner, 'organism' is the 'genus' for animals and plants; this generic essence becomes the specific essence of 'animals' and 'plants' by adding to it the 'differentia' of 'sentient' and 'non-sentient': an 'animal' is a 'sentient

organism,' while a 'plant' is a 'non-sentient organism.' By adding 'living' and 'nonliving' to the genus 'bodily substance,' this genus is made into the two species, 'organic' and 'inorganic.' The generic essence of 'substance' becomes the specific essence of 'body' and 'spirit' by the addition of the 'differentia' of 'material' and 'immaterial.' The differentia, therefore, narrows and limits a genus to a species.

Property: it is a universal idea which *expresses something which flow: necessarily from the essence, though not of the essence itself.* Since the 'property' is considered as something necessarily connected with the essence of a thing, it will have to be present in every member of the class; wherever the essence is found, there also is found this property; it can never be missing. The 'power of speech,' the 'faculty to use tools and to cook food,' the 'ability to laugh,' are properties inherent in man's essence as a 'rational animal,' because they presuppose 'rationality' (intelligence) and 'animality' (bodily structure). The peculiarity of the 'property' is well expressed in the axiom: '*Proprium convenit omni, soli, et semper*; the property applies to *all*, to them *alone*, and *always*.' If this attribute would not apply to every member of the class, or if it were found outside this class, or if it were not always present, it would not be considered a 'property.'

This is taking 'property' in its strictest sense. However, not all philosophers are willing to limit the application of 'property' to so narrow a meaning; they give a wider interpretation to the idea of a 'property.' The philosopher Porphyry, in his *Isagoge*, enumerates four different

interpretations. "Property they divide in four ways: for it is that which happens to some one species alone, though not to every (individual of that species), as to a man to heal, or to geometrize: that also which happens to a whole species, though not to that alone, as to man to be a biped: that again, which happens to a species alone, and to every (individual of it), and at a certain time, as to every man to become gray in old age: in the fourth place, it is that in which it concurs (to happen) to one species alone, and to every (individual of it), and always, as risibility to a man; for though he does not always laugh, yet he is said to be risible, not from his always laughing, but from being naturally adapted to laugh, and this is always inherent in him, in the same way as neighing in a horse." (Chapter 1)

Accident: It is a universal idea *which expresses something of its subject which is neither of its essence nor necessarily connected with its essence, but is merely contingently connected with the essence.* Contingent' is the same as 'not necessary. Anything nonessential, which is not a 'property,' belongs to the predicable 'accident.' If we accept the meaning of 'property' in its strictest sense as something which is found in all members of a species, in them alone and always, then even things like the hands, feet, sex, ears, eyes, nerves, heart, etc., of man would be considered as accidents here. However, no matter what interpretation we place upon the predicable 'property,' certain superadded realities will always have to be classed as 'accidents'; such realities are 'the act of thinking, writing, walking, being well, pleasure, white, virtuous, married, phlegmatic, tall,' etc. Some accidents are

obviously *separable*, as 'the act of walking, sleeping, reading, virtue, sobriety, health,' etc. Others are inseparable accidents, as 'male and female sex, black color in an Ethiopian'; and if we accept 'property' in its strictest sense, then things like 'heart, head, nerves, bones,' etc., would be inseparable accidents.

It should be noted that there is a great difference between 'accident' as a *category* and '*accident*' as a *predicable*. The categorical 'accident' is never a substance, but needs a substance as a subject in which to exist; 'accident' as a predicable is something nonessential, superadded to the essence in such a way that it has *no necessary connection with the essence*. 'Power of speech,' for instance, is not an 'accident' as a predicable, because it is a 'property' of man, necessarily connected with his essence; but 'power of speech' belongs to the category of 'quality,' and 'quality' is one of the nine categories under 'accident.' Even things like beards and tumors, though 'substances' from the standpoint of categories, are only 'accidents' considered as a predicable, because they are only contingently and adventitiously connected with the essence of man. It is unfortunate that the idea of 'accident' is taken in such widely different senses, but the fact is there and the custom of philosophic language will no longer admit of a change.

From this discussion of the various predicables it will be plain that there exists a *hierarchy of genera* and species. A class may be a genus from the standpoint of certain species below it and itself a species with reference to a class above it. 'Body,' for instance, is a species under the genus

‘substance’ and a genus with regard to the species ‘living’ and ‘nonliving’ bodies below it. We, therefore, arrive at the following classification in this hierarchy. The *highest* genus is the one which has no other genus above it. An *intermediate* (subaltern) genus is one which has at least one genus above and below it. The *lowest* genus is one which has species below it, but no genus. The highest species is the species immediately under the highest genus. The intermediate species has at least one species above and below it. The *lowest* species (or the species in the strict sense) is one which has no other species, but only *individuals* below it. A remote genus is one which has species below it, with at least one other genus in between; for instance, ‘a living body’ with regard to ‘man,’ because the genus ‘animal’ lies between the two. A proximate genus is one which is immediately above a certain species; thus, ‘animal’ is the proximate genus of ‘man,’ since no other genus lies between them.

The scale of substantial beings, descending from the highest genus ‘substance’ to the individuals under the lowest species ‘man’ is exemplified in the following arrangement:

The illustration at the right represents the *Tree of Porphyry*. It is named after the philosopher Porphyry, who lived in the third century and who compared the series of genera and species leading from substance to man to the branching of a tree. The relations between the various genera and species can here be seen at a glance. The Porphyrian Tree, of course, exemplifies the scale of beings in the line of *substances*, because these are the broader classifications that interest the philosopher. Each special science, however, has its own classification according to genus, species, differentia, property, and accident. Botany, for instance, which treats exclusively of 'plants,' has its own

genera, species, etc. So also, mathematics, zoology, biology, bacteriology, and all the others.

From the above discussion of the direct universal with its categories and of the logical universal with its predicables, the differences between these two classes of ideas will be more readily understood. The *categories* classify our ideas according to the *things* which they represent, as these things are in their own proper nature. The mere mention of an idea (thing) will be sufficient to place it in its proper category. 'Animal,' for example, belongs to the category of 'substance'; 'height,' to 'quantity'; 'blue,' to 'quality'; 'whipping,' to 'action'; 'cut,' to 'passion'; 'president,' to 'relation'; and so forth. But when I ask, "To what predicable does 'animal' belong?" I cannot answer this question directly, but must ask another question: "To what other idea are you comparing 'animal'?" In other words, a *predicable* is a classification of ideas in their *relation to each other*. To take the example of 'animal,' I would have to formulate a question something like the following: "Under what predicable does 'animal' fall, when compared to 'man' and 'living body'?" The answer would be: "The idea 'animal,' when compared to the idea 'man,' is the 'genus' of 'man'; and when compared to the idea 'living body,' it is a 'species' of 'living body.'" Alone, by itself, no idea can be placed under a predicable; it must first be compared with another idea, and the relation of the two toward each other be established, before we can designate it a 'genus,' or a 'species,' or a 'differentia,' or a 'property,' or an 'accident.'

Having considered the idea under its various aspects and divisions, we must now turn our attention to the term,

the expression of language used to designate the idea.

THE CATEGORIES

This chart represents the *10 categories* (direct universals, or predicaments): Substance, quantity, quality, relation, action, passion, when, where, posture, and habitus. The chart shows the relation between “substance” and the “accidents.” The “accidents,” as will be noticed, are simply *modifications of each individual substance*. This relation between them is real, since it is based on reality as it exists in nature.

The “Porphyrian Tree” restricts itself to the main divisions of the category “substance”; these main divisions are indicated by the *trunk and main branches*.

Each subdivision of a main division can, of course, be worked out in greater detail than is done here; the divisions are merely indicated. But one line of two main divisions has been worked out to its 9 accidents; the others can be worked out in similar fashion.

Everything on the above chart refers to direct universals or categories (not to logical universals or predicables).

CATEGORIES AND PREDICABLES

This chart exemplifies the *relation* between the *categories* and the *predicables*. It will be noticed that predicables can be applied to *any single* item of the categories, whether this item be a “substance” or an “accident.” One item of three of the main divisions of “substance” has been chosen as an

example; and one categorical accident of man, namely “thinking,” has also been selected and the five predicables applied to it.

It will also be noticed that every categorical substance or accident, in order that the predicables may be applied, must *have something said of it*. In other words, a sentence must be made, in which this categorical substance or accident is the “subject;” and the “something said of it” is the “predicate” of this subject. It is then the purpose of the predicables to ascertain in what *relation* this predicate stands to the subject, whether as a *genus*, or a *species*, or a specific *difference*, or a *property*, or an *accident*.

The predicables, therefore, show how (in what manner, whether as genus, species, specific difference, property, or accident) *one idea* (predicate) *can be applied to another* (to the subject); hence, the term “predicable.” These predicables thus express a relation of the mind between *one* idea and *another* idea; such a relation being “logical,” the result of a “reflex” operation of the mind on its own mental act, the predicables are also called *logical* or *reflex* universals.

SUMMARY OF CHAPTER III

Since the classifications and laws of science are expressed in universal ideas, the validity of science depends on the universals as a true representation of reality. Universals represent reality in a true fashion, because the *nature or essence* of things is the same with the sameness of a perfect likeness in all individuals of a class. Therefore the intellect is justified in representing this common nature as a universal. There are two kinds of universals, the direct and the logical universal.

1. The *direct universal* expresses the nature or essence of a thing as it is in itself. The direct universal is divided into ten ultimate classes, called categories: *substance, quantity, quality, relation, action, passion, when, where, posture, habitus*.

2. The *logical universal* expresses the *nature common to many, precisely as it is applicable to many*. It presupposes a comparison between one idea and another and expresses the relationship between them. There are five such relationships, called predicables: genus, species, differentia, property, and accident.

Chapter 4

TERMS

IN OUR MIND AND IN OUR DISCUSSIONS, IDEAS ARE ALWAYS couched in definite words, in written or spoken or mentally pronounced language, in *terms*. It is important to understand these terms and their relation to the ideas for which they stand. The investigation into the nature, use, and classification of terms will furnish some interesting sidelights on the function of language relative to ideas.

NATURE OF TERMS

A *term* is a *sensible conventional sign, expressive of an idea*. This needs an explanation.

A *sign* is something which conveys to the mind a knowledge of something else. Three elements are necessary for a 'sign': the signified thing; the signifying thing; the connection between the two. The signified thing becomes known; the signifying thing makes it known; the connection between the two is the power of the signifying thing to convey knowledge of the signified thing to the mind. There are signs and signs. Some are *formal* signs, based upon a similitude or picturization of the thing signified. Such are

paintings, photographs, drawings, silhouettes, light-images (as in motion pictures), statue portraits. Others are *instrumental* signs, based upon *something else than a similitude*. Since words are not pictures, they are instrumental signs. Some instrumental signs are *natural*, since by their very nature they signify something. Smoke signifies fire; pain signifies a disease or a wound or some systemic irregularity; laughter signifies joy; a distorted face and clenched fists signify anger, etc. Other instrumental signs are *conventional*; their power to signify something is entirely due to convention, usage, agreement, not because of any natural connection between them. There is no earthly natural reason why a pole with red, white, and blue stripes should signify a barber shop, or why red and green lights should signify danger and safety, or why a flag should signify a particular country. Such signs are arbitrary, conventional.

Terms are *conventional* signs. Although it is natural for a man to express his ideas in words, there is no natural connection between the particular combination of vowels and consonants and the thing signified. If there were such a natural connection, then there could be only one language among men, because all men have the same nature; the fact of a diversity of languages proves that the selection of a particular word to signify a particular idea is purely conventional. The animal we call 'horse' could be designated by any other combination of vowels and consonants. In fact, this is the case: the Germans call it 'Pferd,' the French 'cheval,' the Romans 'equus,' the Greeks 'hippos.'

Terms are *sensible* conventional signs. They must be able to be perceived by the sense faculty of man, in order to be styled 'words' or 'terms,' because 'terms' or 'words' are always a combination of vowels and consonants. Written words, of course, always stand for spoken words.

Terms are sensible conventional signs, *expressive of ideas*. It is the very purpose of words or terms to express ideas, and this is the characteristic which distinguishes this kind of sign from all others. Weeping is a sign of grief, laughter is a sign of hilarity; but only words can express the ideas which are the cause of grief and hilarity. Primarily, words are used to convey the *ideas* of one mind to another mind; since, however, ideas stand for things, words have the secondary purpose of conveying information about things to another mind. Viewed from a practical standpoint, of course, we seldom realize that words or terms stand for ideas at all; as a rule, we immediately turn our attention to the things which are (indirectly and secondarily) expressed by the words or terms.

CLASSIFICATION OF TERMS

Having considered the nature of the term, we must next investigate the various kinds of terms. From the standpoint of *perfect* and *imperfect signification*, terms are divided into different classes.

We have univocal, equivocal, and analogous terms. A *univocal* term is one that is constantly used in an *identical sense*. The terms 'man, dog, automobile, sun, gold, mercury, carbon, sulphur,' etc., are such. An *equivocal* term is one

that is used in *entirely different meanings*. For instance, 'pens as an instrument for writing and as an inclosure for animals; 'coach' as a vehicle and as an athletic director; 'page' as a leaf in a book and as an attendant at court. Such terms are equivocal when spoken and written. Others are equivocal when written, but not when spoken; for instance, 'bow' as a knot in a ribbon and 'bow' as a part of a ship. Others are equivocal when spoken, but not when written; as, 'flair' and 'flare.' An *analogous* term is one that is applied to *unlike, but related, things*, so that it is used in a meaning that is partly the same and partly different. There is always some relation between such things, entitling the mind to designate them by the same term; hence, such a term is not equivocal. Due to their partial unlikeness, however, the term is not used in a strictly univocal sense; hence the term is not univocal. An analogous term, therefore, designates related things in such a manner that it applies primarily to one thing and then secondarily to other things.

An analogous term may be based either on an analogy of *proportion* or on an analogy of *attribution*. In the first case the term is applied to unlike things because of some proportion or resemblance existing between them. Metaphors belong to this class. The base of a mountain is called the 'foot' of the mountain because of its resemblance to the position of the foot in a human body; the intellect is called the 'eye' of the soul because of the resemblance of its function to that of the eye in the body. In the case of an analogy of attribution the term is applied in an absolute sense to one thing and is then attributed to other things

because of an intrinsic relation which they have toward the first. 'Health,' for instance, is a condition affecting a living body; here the term is applied in an absolute sense. 'Medicine' is termed 'healthy,' because it restores health; 'complexion' is termed 'healthy,' because it indicates health; 'food' is termed 'healthy,' because it sustains health; 'exercise' is termed 'healthy,' because it promotes health. The term 'healthy,' therefore, is an analogous term, because its meaning in these instances is neither strictly equivocal nor strictly Univocal, but partly the same and partly different.

Furthermore, we distinguish between *fixed* and vague terms. Fixed terms are those whose signification remains the *same*. Terms like 'triangle,' 'man,' 'house,' 'plant,' etc., do not change in meaning. But terms like 'natural,' 'abnormal,' 'good,' 'love,' 'sickness,' 'bright,' etc., are subject to many shades and degrees of meaning; they are vague terms, because their meaning *shifts* according to the *viewpoint* and use of the *individual* speaker.

From the standpoint of the *comprehension of the idea* expressed by the term, we have various divisions of terms.

One such is the division into positive and negative terms. A positive term is one which signifies a real, *actual* thing, for instance, 'God,' 'earth,' 'rose,' 'germ,' 'pencil,' 'star,' 'light.' A negative term signifies the *absence of a thing*; as 'darkness,' 'death,' 'blindness,' 'ignorance,' 'sterility.' Some terms are negative in form, but really positive in meaning, as 'immaterial,' 'infinite,' 'uncreated,' 'immortal.' Others are positive in form, but negative in meaning, as 'sin,' 'death,'

'sterile,' 'dark'; the words show no negation although they mean the absence of something.

Another distinction divides terms into *concrete* and *abstract*, in as much as they stand for concrete or abstract ideas. 'Man' and 'white' are, therefore, concrete terms, while 'humanity' and 'whiteness' are abstract.

Then we have simple and compound terms. A *simple* (in-complex) term consists of a single word, as 'being,' 'philosopher,' 'lawyer,' 'house,' 'humanity,' 'mind.' A *compound* (complex) term consists of more than one word, like 'court house,' 'mortal man,' 'the President of the United States,' 'the playing child,' 'the cold snow,' etc.

Again, we distinguish between *connex* and *disparate* terms, in as much as they express connex or disparate ideas. 'Mother — child,' and 'teacher — pupil' are connex; 'man — healthy' and 'dog — sleeping' are disparate.

Similarly, we have *real* terms (terms of 'first intention') and *logical* terms (terms of 'second intention'), expressing real or logical ideas. 'Dog,' 'house,' 'car,' are real terms; 'genus,' 'predicate,' 'category' are logical terms.

Considered from the standpoint of the *extension of the ideas* expressed by the term, we divide terms into singular, universal, particular, and collective. The understanding of these terms should cause no difficulty. A singular term applies to one individual only. This can be done by using a proper name, like 'Napoleon, Louis Pasteur, Franklin Roosevelt,' or by prefixing a demonstrative pronoun, as 'that automobile, this house'; or by using some restrictive qualification, as 'the discoverer of X-rays,' 'of radium'; or by

an enumeration of the 'individuating characteristics' of form, figure, place, time, ancestry, country, and name.

A universal term, of course, is one which expresses a universal idea and can be applied to each individual of a class and to the class itself; such are the terms 'man,' 'tree,' 'street,' 'star,' 'desk,' 'book,' etc.

A particular term is a universal term taken partly and indeterminately. Words like 'some,' 'many,' 'a portion of,' 'certain,' when added to a universal term, make it particular; as when we say 'Certain automobiles are costly,' 'some men are redheads,' 'many children are good,' 'a portion of the money was lost.'

A collective term stands for a collective idea, one that represents a class, but does not apply to the individuals of the class taken singularly. 'Family,' 'army,' 'government,' 'flock,' 'heap,' etc., are such.

SUPPOSITION OF TERMS

All terms have a definite meaning. Nevertheless, this meaning can be taken in different ways, depending upon the *use* to which we put the terms; and this use is not always the same. Logicians call this the 'supposition' of a term. The *supposition is the use of a term for the thing which it signifies*. We cannot always produce the actual thing we wish to discuss, and so we make use of words or terms to stand for (*sub-ponere, suppositio*) the thing itself. This necessitates a clear understanding of the *use* of terms, for after all, everything depends upon the meaning we give to terms.

The supposition of a term may be either *material or formal*. It is material when we consider it merely as a word, without any regard to its inherent meaning. When I say 'man is a 'monosyllable' or a 'noun,' I am obviously not considering its inherent meaning. When, however, I consider it according to its signification, then I take the term in its *formal* supposition *as a term*; for instance, 'Man is a rational animal.'

This formal supposition will be either *real or logical*. It is real, when the term is used for a thing in its natural being or existence; as, 'Man is a living substance.' But if I use the term according to its logical existence in the operations of the mind, it is logical; as when I say 'Man is the "species" of all the individuals in its class.'

The real supposition may be either *absolute or personal*. It will be absolute, when the term designates merely the nature as such, without any reference to the individuals who are the bearers of this nature. It is in this sense that we use the term 'man,' when we state: 'Man is mortal.' But when the term signifies both the *nature and the bearers* of this common nature, then the supposition is personal. For instance, 'All men are mortal,' '*every horse* is an animal'; 'all' and 'every' make it personal.

The personal supposition of a term is again subdivided into a *distributive* and *collective* supposition. It is distributive, when the term is used for all the individuals taken *singly* and *together*, as in the sentence 'All men are mortal,' because we mean to assert that each and every man and all taken together are mortal. It is collective, when the term applies to all *taken together*, but not to them taken

singly; thus, the statement 'All parts equal the total' is true when I take the term 'all parts' together, but one cannot say that 'each single part' will 'equal the total,' because that is not the meaning and it is obviously false. Even in the distributive supposition of a term, however, one must be careful. At times this supposition will apply in a *completely* distributive sense, including all *individuals, species and genera* of the class, as when we assert that 'Every living thing is a substance.' At other times it will apply only to the *species and genera* of a class, but *not* to the individuals; for example, 'Every land animal was present in the ark of Noah,' meaning only the species and genera, but not the individuals.

At first blush it may seem as if the enumeration and explanation of these various types and suppositions of terms can be of no particular practical value. To judge in this fashion would be a serious error. We must bear in mind that terms stand for ideas, just as ideas stand for things. They therefore form the warp and woof of the fabric of our knowledge. If logic is to be of assistance to us in the science of correct thinking, we must first acquire a thorough understanding of the *materials* which we must use in forming judgments and argumentations, because only through judgments and argumentations can we discover hidden truths of more than obvious value. Much confusion and many errors in argumentations would be avoided, if ideas and terms were always clear and if the exact meaning of ideas and terms were constantly retained in the course of a discussion. The subject matter of philosophy is so deep

and difficult in itself, that it should not be complicated by the vagueness of ideas and the unsettled use of terms.

SUMMARY OF CHAPTER IV

A term is a sensible conventional sign, expressive of an idea. Terms are of many kinds.

1. From the standpoint of *perfect* and *imperfect* signification, terms are univocal, equivocal, or analogous. A univocal term is one that is constantly used in an identical sense. An equivocal term is one that is used in entirely different meanings. An analogous term is one that is applied to unlike, but related, things, so that it is used in a meaning that is partly the same and partly different. Then, too, we have fixed and vague terms.

From the standpoint of the *comprehension* of the idea expressed, we distinguish between positive and negative terms, concrete and abstract terms, simple and compound terms, connex and disparate terms.

From the standpoint of the *extension* of the idea expressed, we have singular, universal, particular, and collective terms.

2. The *supposition* of a term is its use for the thing which it signifies. This use varies.

The supposition of a term will be material, or formal; the formal supposition is either logical or real; the real supposition is either absolute or personal; the personal supposition is either distributive or collective; and the distributive supposition may be either completely or incompletely distributive.

Chapter 5

DEFINITION AND DIVISION

CLEARNESS OF IDEAS IS ESSENTIAL TO CORRECT THINKING. THE greatest obstacle to the pursuit of truth lies in the vagueness and confusedness of ideas. Ideas will be clear when the mind has an accurate knowledge of their comprehension and extension. The comprehension tells us what the idea implies, what essential attributes it contains in itself, what information it has concerning the thing it represents; the extension gives us the application of the idea to the individuals, shows us how and in how many objects the idea is realized, delimits the extent of the field in which this idea can be found. Two important processes for gauging the comprehension and extension of ideas are definition and division.

DEFINITION

By *definition* we understand a *statement which explains what a thing is*. It answers the question: "What is this thing?" We can give the answer when we know the *comprehension* of the idea which represents this thing. Since, however, the reality of the thing exists before we

form an idea of it, and since the idea is an intellectual image of the thing, it stands to reason that we must first obtain an accurate knowledge of the *thing itself*, before we can give an accurate definition of it. The ideal definition would be one which would reveal to us the complete nature of things and classes in their essentials and nonessentials; the limited character of our knowledge, however, makes this a practical impossibility, and as a result we must often be satisfied with incomplete and relatively inadequate definitions. In consequence of this there are different kinds of definitions.

We distinguish, first of all, between nominal and real definitions. A *nominal* definition explains *what a word means*, while a *real* definition explains *what a thing is*. At times a word or term may be unclear or ambiguous, or it may be used in some special technical sense in a particular science, or the speaker may wish it understood in a definite meaning in his discussion in order to avoid verbal disputes. A nominal definition is a legitimate definition in these cases, because words or terms are 'signs,' and it may be necessary to explain their signification, since that is precisely what 'signs' mean.

On freight cars, during the World War in France, soldiers saw the painted words 'Huit Chevaux, Quarante Hommes,' and asked, 'What does that mean?' The answer 'Eight Horses, Forty Men' was a nominal definition. Similarly, if I define a 'bi-linguist' as 'one who speaks two languages.' So, too, when the philosopher says: 'By "accident" I understand "a being which needs a subject to exist in,"' he explains the sense of a technical term. And when a speaker states that

he wishes the term 'soul' to mean 'the vital principle in an organized body,' he merely desires to specify the meaning of the term 'soul' so as to avoid confusion in his discussion. Of course, in the last two instances mentioned, the definition of the term also involves an explanation of the thing represented by the term, but the primary purpose is merely to indicate the meaning of the term as such.

A *real* definition is a *statement explaining what a thing is in itself*. The perfect real definition would be one which briefly but fully explains the essential nature of a thing. This, however, in most cases, is a goal far beyond the reach of man, since the different kinds of beings in the world are so vast in number and so complex in structure and operation, that man's mind can seldom distinguish between their essentials and nonessentials.

An *essential* (*quidditative*) definition is a statement which explains *the essence or nature of a thing*. It will be essential when we can define a thing by its *proximate genus* and *specific differentia*. This is the perfect definition. The proximate genus includes within its comprehension all the essential elements of the genera above it and therefore includes all the beings that are cognate or similar in nature to the thing which is to be defined; the specific differentia, on the other hand, brings in the distinctive element which separates this thing from all others of a similar nature, by showing in what manner it is different from all others, with which it might be erroneously identified. Take as example 'man.' 'Man' is defined as a 'rational animal'; 'animal' is his proximate genus, 'rational' is his specific differentia. The proximate genus 'animal' includes within its comprehension

all the essential elements of the genera above it, because an 'animal' is a 'sentient, living, material substance'; and this shows all the beings which are in some way similar to man — brutes, plants, inanimate bodies, substances. The specific differentia 'rational' is the one distinctive essential element which distinguishes man from every other 'animal'; it thereby makes him a species of his own and separates him from every other 'animal' and every other genus above 'animal,' including plants, inanimate bodies, and substances. Furthermore, since the specific differentia is the distinctive element in the essence of man, it includes all the characteristic 'properties' which lie in the nature of man *as man*, namely, power of speech, free will, morality, social life, government, religion, immortality, etc. — realities which are absent in all other beings in this physical world.

We can make such essential definitions also of the genera above man up to substance. But when we attempt an essential definition of the various kinds of brutes, plants, and bodies, we fail, because we are unable to recognize the particular essential element which distinguishes, for instance, the horse from the dog, the rose from the lily, oxygen from hydrogen. In these cases, unfortunately, the limitation of our intellectual powers forces us to be content with a descriptive definition.

A ***descriptive*** definition is a statement which explains what a thing is in itself by enumerating the *positive, but nonessential, elements of its nature*. As a rule, the physical sciences and natural history cannot go beyond a descriptive definition. Even in this type not all are of the same value.

We distinguish between distinctive, genetic, causal, and accidental definitions.

A **distinctive** definition is one which explains a thing *by its properties*. 'Property' here is taken in its strict sense as something necessarily connected with the essence, without being of the essence itself. This definition approaches closest to the essential definition and is, therefore, next in importance to it. When I say that man is an 'animal capable of articulated speech,' an 'animal using tools,' an 'animal that can cook its food,' an 'animal capable of morality,' then I am defining 'man' by means of a genus and a property. In a like manner, physicists define, for example, 'oxygen' as 'a colorless, odorless, tasteless gas, 1.105 times as heavy as air, liquefiable at and below -118° C'; this defines oxygen by its 'properties.'

A **genetic** definition explains a thing by its *process of origin or production*. Thus, I can define 'water' as a 'body resulting from the combination of two atoms of hydrogen with one atom of oxygen'; a 'circle' as 'a geometrical figure constructed by the revolution of a straight line in a plane round one of its extremities'; a 'lunar eclipse' as 'a shutting off of the light of the moon produced by the interposition of the earth between moon and sun.' These are scientific definitions, accurate and expressive enough, but they tell us nothing of the intrinsic essence of the things defined.

A **causal** definition is the explanation of a thing by means of *its efficient or final causes*. 'Efficient' causes are causes which produce a thing; 'final' cause are the end, the purpose, on account of which a thing is produced. Thus, the 'human soul' can be defined as 'an immaterial substance

created by God'; a 'painting' is 'a picture in colors produced by an artist.' These definitions are based on efficient causes. Here are examples of definitions based on final causes or purposes: 'A watch is a mechanical device to indicate the hours of the day,' 'the ear is a bodily organ constructed to perceive sound waves.'

An ***accidental*** definition is an explanation of a thing based on characteristics which are *neither essential nor necessarily connected with the essence*. This is rather a description than a definition properly so called. The subclasses of the natural sciences and all individuals are defined this way. We have numerous examples of this kind in police circulars describing wanted criminals. For instance: 'John Walter, alias Joseph Brown; age, 42 years; height, 5 ft. 10 in.; weight, 158 pounds; hair, black; complexion, sallow; eyes, brown; two gold teeth, upper front left; first joint right index finger missing; scar, crescent-shaped, on left cheek; race, white.'

When speaking of definitions, one must always bear in mind that certain terms and ideas and things are *incapable of definition*. They can be known, but not defined. Some qualities are so *simple* in character that they cannot be analyzed, but only experienced; such are the elemental qualities of heat, color, pleasure, pain, tone, taste, etc. One can give another a piece of sugar to taste and say: 'That is sweet'; a pickle, and say: 'That is sour'; show him sealing wax and say: 'That is red'; pinch him and say: 'That is pain'; burn him and say: 'That is heat.' But no amount of words will enable a man born blind to understand the 'red' of a rose or the 'blue' of the sky or the 'light' of the moon. Some

ideas are so *general* that they cannot be defined by a strict definition. The supreme genera 'substance' and 'accident' are such. The genus above them would be 'being.' However, 'being' cannot be a 'genus.' For a strict definition a specific differentia would have to be found which lies *outside* the comprehension of 'being'; but the only thing outside the comprehension of 'being' would be 'non-being' or 'nothing;' and 'nothing' is, of course, no differentia for anything. Supreme and fundamental ideas like 'substance,' 'accident,' 'being,' 'one,' 'thing,' etc., admit of no strict definition and are therefore called *transcendental*. More will be said of these in metaphysics.

RULES OF DEFINITION

In order that a definition be correct, certain *rules* will have to be observed. They are indicated by the very nature of the definition.

The definition must be *clearer than the thing defined*; otherwise it loses its 'Value, since it is the purpose of the definition to lead the mind from the known to the unknown and to remove the obscurity of ideas by explaining them. Hence, *metaphorical* expressions must be avoided; for instance, 'Man is the king of creation,' 'the lion is the lord of beasts.' Words should not be used which are more unusual than the idea to be explained; it would thus be wrong to define a 'lie' as an 'intentional terminological inexactitude,' and a 'liar' as a 'person whose sinuosity of speech is due to a superficial succedaneum for veracious reality.' A 'blush,' of course is a 'reddening of the cheeks due to modesty,

shame, or embarrassment,' but some wag preferred to define it as 'a temporary erythema and calorific effulgence of the physiognomy, aetiolized by the perceptiveness of the sensorium, in a predicament of inequilibrium, from a sense of shame, anger, or other cause, eventuating in a paresis of the vaso-motorial, muscular filaments of the facial capillaries, whereby, being divested of their elasticity, they become suffused with a radiance emanating from an intimidated praecordia.' Such a definition is, of course, absurd; nevertheless, science is entitled to define its ideas in technical terms which, though unintelligible to the lay mind, are clear and exact for the professional scientist for whose benefit the explanation is intended. Witness Herbert Spencer's famous definition of evolution: 'Evolution is an integration of matter and a concomitant dissipation of motion; during which the matter passes from an indefinite, incoherent homogeneity to a definite, coherent heterogeneity; and during which the retained motion undergoes a parallel transformation.' Though the ordinary reader may stare at such a definition, it is a perfectly legitimate explanation when addressed to the instructed scientific student.

Another rule is, that the definition must *not contain the idea to be defined*, because in that case an attempt is made to explain something by itself, while the thing itself needs explaining. The definition of 'man' as 'homo sapiens' is faulty from this standpoint, because 'homo' is the Latin equivalent for the English term 'man.' It is a violation of this rule to make a '*circular definition*,' i.e., when a first idea is defined by a second, and then the second is defined by the

first. Thus, if we define a 'dollar' as 'one hundred cents' and then define a 'cent' as 'the hundredth part of a dollar,' we are guilty of a circular definition. Were we to attempt to define the transcendental idea 'being' as a 'thing' or 'something that is not nothing,' we would include the idea to be defined in its definition; such words and phrases, together with examples, will assist in making the idea clear, but they must not be considered real definitions.

Again, the definition must be *convertible with the idea defined*; by this is meant, that the definition must neither be wider nor narrower in comprehension than the comprehension of the idea defined. This should be obvious. If the definition is an explanation of the idea or thing defined, then both must be identical in meaning, and it should make no difference if we interchange them as subject and predicate in a sentence. Since 'Man is a rational animal,' it must be equally true that 'A rational animal is a man'; if 'An animal is a sentient, living, bodily substance,' then 'a sentient, living, bodily substance' must also be an animal.' The definition of 'logic' as 'the science of reasoning' is too narrow, because other mental processes (the formation of ideas and judgments) also belong to logic; the definition of 'logic' as 'the science which guides the mind to truth' is too wide, since all sciences do that.

Lastly, the definition must be *positive*, not *negative*, whenever possible. The definition should explain what the thing is; to give a negative definition would merely explain what the thing *is not*, without any real explanation of its nature in itself. It would thus be faulty to define 'health' as the 'absence of sickness,' or 'truth' as the 'opposite of

error,' because I cannot know what 'sickness' or 'errors means without a prior knowledge of 'health' and 'truth.' Of course, if the idea to be defined is a *negative or privative idea*, it can be defined in no other way than by stating that it is the negation or privation of some reality. It will, therefore, be perfectly legitimate to define 'sickness' as the 'privation of health,' and 'error' as the 'opposite of truth,' and 'darkness' as the 'absence of light.'

In connection with this last rule, it must be borne in mind that some terms are negative in form but positive in meaning; and as such they demand a positive definition. 'Immortality' is negative, as far as the form of the term is concerned, since the word means literally 'non-mortality'; but its meaning denotes a positive perfection, which should be defined in a positive fashion as 'everlasting duration of existence.' Words like infinite,' 'immense,' etc., presuppose positive reality and should be defined in positive terms; but the mind of man is too imperfect to be able to grasp the fullness of the reality implied by these ideas, and so it can define them only imperfectly. In such instances we define the idea best by stating the positive perfection and denying all limitation of this perfection; as, 'infinite' means 'possessing perfection beyond all degrees without limit,' and 'immense' means 'possessing magnitude without limit.'

DIVISION

Besides definition we have a second method of making ideas clear and arriving at a better understanding of their meaning, the method of division. By *division* we mean the

resolving of a whole into its parts. Something is a 'whole' when it consists of parts which are bound together into some sort of unity; and since the 'whole' consists of parts, it can be resolved or broken up into these component parts. Naturally, then, there will be as many kinds of divisions as there are kinds of parts united into a whole or totality. Logic, of course, is concerned with ideas as intellectual images of things, but mainly with ideas as ideas. We, therefore, distinguish between real division and logical division.

A *real* (actual) division is the *resolution of a thing into the natural part which it has independent of the mind.* These parts are twofold, physical and metaphysical, and this makes us distinguish between a physical and metaphysical division.

The *physical* parts of a thing are *mutually distinct and separable* and belong to the *very nature of the thing.* Of these some are essential parts; that is to say, they are so necessary to the being, that, if any one be missing, the thing will cease to be that particular being, because these parts conjointly make it to be what it is. The essential parts, for instance, of 'man' are his 'body' and 'soul'; these parts are mutually distinct, are separable (by death), and belong to the very essence of man. 'Water' consists of 'oxygen' and 'hydrogen'; without either of these two elements 'water' would cease to be 'water.' Table salt is a combination of 'sodium' and 'chloride,' and without both 'salt' cannot subsist and retain its being as 'salt.' Other parts are *integral* parts; they belong to the nature of the thing, but the absence of one or the other or of some of them would

not destroy the essence of the being and make it cease to be what it is. Such integral parts in 'man' are his hands, arms, feet, legs, eyes, ears, ribs, muscles, nerves, bones, etc.; in a 'tree' they are the roots, stem, branches, leaves, blossoms, fruit, bark, fibers, etc. If these integral parts are of the same kind throughout, they are called *homogeneous* parts; 'water' consists of many drops, each drop being 'water,' and 'sulphur' in a lump can be divided into many portions, each of which is 'sulphur,' and a block of 'hickory wood' can be cut into many pieces, each piece being 'hickory.' But if these parts are *not* of the same kind, they are called *heterogeneous* parts; the various parts of man's body (arms, eyes, hair, bones, nerves, etc.) are such, and so, too, are the parts of a plant (roots, stem, leaves, flowers). A mere glance at these integral parts will show that some of them may be missing without destroying the essence of the being as such; a man would still be a 'man,' even if his arms or legs or eyes or ears were removed, and a 'tree' would still be a 'tree,' even if the blossoms or fruit or leaves or branches were cut off. The (mental) division of things *into their component physical parts* (whether they be essential or integral) is called a *physical* division.

Besides physical parts a thing also has *metaphysical* parts. These parts actually constitute the *essence* of a thing, but they are *not separable* from each other, because in an individual they constitute one single *identical nature*. This may seem a paradox, if not a contradiction. If they are parts, why are they not separable? A close attention to the following will explain the situation.

The metaphysical parts of a being are the various *grades of being* contained in the comprehension of the idea of the thing. 'Man,' as we know, is a 'rational, sentient, living, bodily substance'; these five 'grades of being' form the metaphysical parts of man's essence or nature. We have, therefore, divided the *idea* of 'man' into five distinct and different *ideas* which compose the comprehension; we have also thereby divided 'man' *himself* into his five metaphysical *parts*, because 'man' himself consists of these various 'grades of being,' independent of the mind. However, are these 'grades of being' or metaphysical parts so distinct from each other as *entities* in man as found in the physical order of the world, that they are actually *separable* from each other? They are *not*. Body and soul, of course, are separable in man, and death actually makes such a separation. In like manner, the legs, arms, eyes, ears, bones, etc., are distinct as entities from each other, and can be separated one from the other, and from the body itself. 'Rationality,' 'sentientcy,' 'life,' 'body,' and 'substance' are not distinct entities, separable from each other, in the nature of man, like coins in a purse, or segments of pulp in an orange, or peas in a pod; they are *not* actually five *entities* forming the essence of 'man,' but *one single nature* consisting of five 'grades of being' inseparable from each other.

Here is the reason. In man the 'body' *is* his 'substance'; they are one and the same *thing* in man; they cannot be separated in man, so that after the division there would be two distinct entities, 'body' and 'substance'; man is simply a 'bodily substance.' Similarly, 'life' in man and his 'bodily substance' cannot be divided, so that after the division

there would be two separate entities; man's 'life' is his 'bodily substance' itself which grows by taking in food and assimilating it; his 'bodily substance' is, therefore, a 'living, bodily substance,' and 'life' and 'bodily substance' are one and the same reality, one and the same essence or nature. So, too, the 'animal' in man and his 'living, bodily substance' cannot be actually removed from each other, so that after the division there would be the 'animal' on the one side and the 'living, bodily substance' on the other the 'animal' in man is nothing else but the 'living, bodily substance' which feels and sees and hears and smells and tastes and walks; his 'animality' is identical with his 'living, bodily substance,' inseparable and indivisible. In like manner, man's 'sentient, living, bodily substance' is the selfsame entity which also thinks and reasons, and which is, therefore, 'rational.' Man does not consist of five distinct and separable entities, but has *one nature* manifesting itself in *five different ways*. In other words, considering 'man' as an actual being, his 'substance' is at one and the same time 'bodily, living, sentient, and rational'; man's nature, therefore, *is one single substance*; and the five 'grades of being' are one single entity consisting of five inseparable metaphysical parts. The reason is obvious; parts, which at bottom are *identical*, cannot be separated from each other in *fact*.

Now then, this being the case, how does it happen that the mind *in its thought* divides the metaphysical whole of the essence into such distinct and *apparently separable* parts? The mind does this because, although these 'grades of being' are inseparable in this individual nature, they can be, and often actually are, found *separated* (separately

realized) in *different* kinds of beings. Let us take the example of man's essence again. The mind divides this essence into five 'grades of being,' namely 'substance, body, life, sentiency, rationality.' In 'man' these five are inseparably fused together to make one nature.

But they need not always be found together as they are found together in 'man.' The idea of 'substance' is realized in God, but God is not a 'bodily' substance. We also find 'bodily substances' which are not 'living'; such are the minerals of the earth. Some 'living, bodily substances' are not 'sentient,' as plants.' Many 'sentient, living, bodily substances' are not 'rational'; we see this in the brutes. Only in 'man' do we find the five grades of 'rationality, sentiency, life, body, and substance' united into a single identical essence. These five 'grades of being' are, therefore, real enough in man's essence to be considered as parts. Since, however, they cannot be separated from each other in *fact*, but only in *thought*, they form a higher unity among themselves than the physical parts of an essence.

The parts of an essence which are the '*grades of being*' of one concrete nature (in reality identical and inseparable, but distinct and separable in thought) are called *metaphysical* parts; and the whole which consists of metaphysical parts is called a metaphysical whole. The *division*, then, which divides an essence into its metaphysical parts, is styled a *metaphysical division*.

In real division (physical and metaphysical) the mind divides the whole into its component parts, in as far as the thing itself has parts, independent of the mind. In a logical division the mind divides a 'logical whole' into its

component parts; and the 'logical whole' is a universal idea as universal.

We define *logical division* as the *resolving of a universal idea into the members which constitute its extension*. It will be readily understood that a logical division is neither more nor less than the resolution of a *class* into the component *subclasses or individuals* which fall under this particular class-name. The class is conceived by the mind as a unit, a whole, a totality; the subclasses and individuals are the parts which, united together in the universal idea, form the unity of a 'whole.' We divide, for instance, the universal idea of 'substance' into 'material substance (body)' and 'immaterial substance' and all their subclasses; the universal idea of 'bodily substance' into 'living, bodily substance' and 'inanimate, bodily substance' and all their subclasses; the universal idea of 'living, bodily substance' into 'sentient, living, bodily substance' and 'non-sentient, living, bodily substance' and all their subclasses; the universal idea of 'sentient, living, bodily substance' into 'rational' and 'irrational'; and these latter we divide into their individual members.

It will have been noted that in dividing and subdividing a universal into its members, we always *add* an element to the comprehension of the foregoing class; thus, in dividing the class 'substance' into its next members or subclasses, we add the elements 'material' and 'immaterial'; and so with the others. A logical division is therefore made by the *addition* of some element, by a *composition*; such a composition is styled synthesis. Reversely, in a real division

we break up the comprehension and *take it apart*; this process is called *analysis*.

RULES OF DIVISION

As in the case of the definition, logicians prescribe certain *rules* which must be observed in the division, in order that it fulfill its purpose of making ideas clear and accurate for science and general knowledge.

First of all, a division should be *adequate*; this means that all the *parts taken together must equal the whole*. This general rule involves a number of particular rules.

No part may be omitted; otherwise the division would be incomplete and therefore faulty. The division of American politicians into Republicans and Democrats would be inadequate, because it omits Socialists, Communists, Progressives, Prohibitionists, and possibly others. The division of the senses of man into 'taste, sight, smell, hearing, and feeling' would omit the imagination, sense-memory, inner central sense, and instinct.

No member of the division may equal or exceed the whole; because a part can never equal, much less exceed, the whole. It would be a violation of this rule to divide 'animals' into 'sentient' and 'rational,' because 'sentient' is the same as 'animal'; and it would be worse to divide 'animals' into 'sentient' and 'living,' because 'living' has a wider extension than 'animal.'

No member may include the other; because the parts must be distinct and exclusive among themselves, otherwise such a division would enumerate more parts than the whole

really contains. One cannot, for instance, correctly divide the 'Immigrants of the United States' into such classes as 'Europeans, Asiatics, Englishmen, Germans, Italians, Frenchmen, Africans, Russians, and Chinese.' Some of these members of the division are already included in wider members; thus, 'Englishmen, Germans, Italians, Frenchmen, and Russians' are included in 'Europeans,' while 'Chinese' and some 'Russians' belong to the 'Asiatics.' In order to avoid such erroneous divisions one should establish a *fixed principle* or standpoint of division and adhere to it throughout.

The other general rule is: the *division should be clear*.

Hence, a division should be *orderly*. This means that we must not leap from a higher to a lower class and omit a middle class; the division should be a gradual process, going from one class to its immediate subclasses, and from one subclass to the next, and so on. It would be faulty to divide 'substance' into 'living' and 'nonliving,' because that would skip the intermediate classes 'material' and 'immaterial.' So, too, it would not be a good division to divide 'animals' into 'men, birds, reptiles, insects, fish, and mammals,' because the next members of 'animals' are 'men' and 'brutes.'

A division should also be *reasonably limited in members*. To enumerate a veritable catalog of members is both unnecessary and confusing. Were one to divide the class 'fish' by producing a list of a few hundred names, the division would be useless. All that would be necessary would be to enumerate the main classes and then subdivide each supreme class into its main subclasses. It is here that

the *classification* of science enters the field and brings order into chaos.

With definition and division we close our examination into the nature and the various kinds of ideas, and we now pass on to the judgment.

SUMMARY OF CHAPTER V

1. A *definition* is a *statement which explains what a thing is*. The *nominal* definition explains what a word means; *real* definition explains what a thing is in itself.

The real definition is *essential*, when it explains the essence of a thing by proximate genus and specific differentia. It will be *descriptive*, when it explains a thing by the positive, but nonessential, elements of its nature; and this descriptive definition will be either distinctive or genetic or causal or accidental.

Rules for definition: it must be clearer than the thing defined; must not contain the idea to be defined; must be convertible with the idea defined; must be positive.

2. *Division* is the *resolving of a whole into its parts*. There are two main kinds: real and logical.

A *real* division is the resolution of a thing into its natural parts. If these are physical, we have a physical (essential or integral) 'division. If the parts are metaphysical ('grades of being'), they have a metaphysical division.

A *logical* division resolves a universal idea into its members. A logical division is always a 'synthesis,' while a real division is always an 'analysis.'

Rules for division: it must be adequate and clear. A division is *adequate*, when the parts taken together coincide with the whole. Hence: no part may be omitted; no member may equal or exceed the whole; no member may include the other. It will be *clear*, when it is orderly and reasonably limited in members.

PART II

JUDGMENT AND PROPOSITION

Chapter 6

NATURE OF JUDGMENT AND PROPOSITION

IDEAS ARE THE RAW MATERIALS OF KNOWLEDGE, THE BUILDING stones of truth. But just as the raw materials are not the finished product and building stones are not the completed edifice, so ideas as such are not an expression of truth. Ideas in themselves are neither true nor false; they are indifferent to truth and error. A thousand ideas may flash upon my mind, like pictures upon a screen, but truth will be absent until I halt two of them, compare them, and express an agreement or disagreement between them: then I have truth or error.

Thus, I may walk along the avenue and a number of ideas will jostle each other in my mind: street, lawn, flowers, houses, stores, cars, men, women, children, churches, museum, theater, policeman, magazines, newspapers, drugs, clothing, shoes, and ten thousand other ideas of things I perceive. Are they 'true' or 'false'? There is nothing in them so far that could possibly be called 'true' or 'false.' My mind, however, does not stop at letting these ideas parade before itself. It goes farther. It does something. It says something (mentally) of these things. 'That car is going at least thirty-five miles an hour.' 'The

policeman is changing traffic.' 'That man is blind.' 'These children are happy.' 'The library is open.' 'Prices are low.' 'The flowers are withered.' 'There is no large crowd out today.' 'My feet hurt.' 'The wind is blowing.' 'It is getting colder.' 'The sky is not dark.' 'The sun is shining.'

NATURE OF JUDGMENT

Are these things really as my mind judges them to be? If they are, then my mind has expressed a truth; if they are not, then it has expressed a falsity. If these judgments of my mind agree with the facts, they are true; otherwise they are false. *Truth and falsity*, then, *lie in the judgment* and not in the ideas taken alone for themselves. One can speak of truth or falsity only then, when two ideas are placed side by side in the mind and some judgment is made about them. And a *judgment* is an *act of the mind pronouncing the agreement or disagreement of ideas among themselves*; or, in other words, it is an *act of the intellect affirming or denying one idea of another*.

The judgment will always appear in one of these two ways: it will either affirm or deny one idea of another. When I make the judgment that 'My feet hurt,' I *affirm the agreement* between the ideas 'my feet' and 'hurt' in my thought. And when I assert that 'The sky is not dark,' I *deny the agreement* (affirm the disagreement) between the ideas 'sky' and 'dark' in my thought. Both judgments will be true, if they are really *as stated*; contrariwise, they are false.

Three things will therefore be necessary for the *making of a judgment*. *First*, the mind must have an understanding

of the two ideas about which it intends to make a judgment. Unless it know them, it can say nothing about them. Is 'Anacin' a drug? Even if I know that Anacin is a 'compound of pure acetphenetidin, acetylsalicylic acid, caffen alkaloid, and quinine sulphate,' I will not be able to judge that 'Anacin is (or is not) a drug' so long as these brain-twisting words given in explanation are as cryptic and mysterious to me as the hieroglyphics on the sarcophagus of some ancient Egyptian Pharaoh. But when I take the two ideas 'man' and 'animal,' both ideas are familiar to me and I have an understanding of their meaning, so that I am able to think intelligently of them and unite them into a judgment. *Second*, the mind must compare the two ideas in question, study the comprehension of each, recognize their identity or nonidentity, and thus be ready to pronounce an agreement or disagreement between them. Comparing the idea of 'animal' as a 'sentient, living, bodily substance' with the idea of 'man' as a 'rational, sentient, living, bodily substance,' I recognize the fact that the whole comprehension of 'animal' is contained in the comprehension of 'man' and I am ready to pronounce their agreement. *Third*, the mind must express in a mental act the agreement or disagreement between the two ideas compared together. It is precisely this mental *pronouncement* of agreement or disagreement between two ideas which constitutes the *essence of the judgment*. Everything up to this point was mere preparation. The mind now makes the definite judgment: 'All men are animals.' Here, then, we have an expression of truth and the possibility of an advancement of knowledge.

Of course, if I make such obvious judgments as 'The sky is blue' and 'The weather is cold today,' I am not expressing any world-startling truth nor am I advancing knowledge to any appreciable degree. But when science, after decades of ingenious experiments and intricate astronomical calculations, had arrived at the definite judgment that 'The earth revolves around the sun' and that 'Our planetary system is heliocentric,' it made a definite advancement of knowledge. No astounding truth is expressed in the judgment that 'Sunlight is bright'; but the scientific statement that 'Sunlight travels at the rate of over 186,000 miles per second' proved to be of great value to knowledge, because it gave an exact yardstick to astronomy with which to measure the distance of stars and interstellar space. To state that 'Cows cannot smile' may seem like a humorous quip, but to go a step farther and express the philosophic judgment that 'No animal but man is rational' is a truth of great importance to mankind; and so on, indefinitely. Some judgments, therefore, are the result of a simple comparison of two ideas; others, like the laws of science, are the product of centuries of mental toil and the achievement of a million experiments in the field of research. In all these cases, however, truth is contained in the judgment.

Three elements, then, enter into the composition of a judgment: two ideas, and the mental act pronouncing their agreement or disagreement. One idea, the subject-idea, has something *said about it*; and the other, the predicate-idea, contains the 'something' which *is said about* the other. In the judgment 'The weather is cold,' it is the subject-idea 'weather' about which something is stated and the

predicate- idea 'cold' is the 'something' which is stated about the weather. These two compared ideas are the *matter* of the judgment, because they are the materials or objects which enter into composition in the judgment. The mental pronouncement of the agreement or disagreement between the two compared ideas is the *form* of the judgment, because this pronouncement constitutes the very essence of the judgment as a judgment, distinguishing it from every other operation of the mind, such as the idea or the argumentation. Looked at from the standpoint of its matter, the judgment is a composition of two distinct elements, the ideas; but from the standpoint of its form, the pronouncement, it is a simple intellectual act fusing the two ideas into one. Such is the nature of the judgment.

Truth and error, as has been stated, lie in the judgment; no other act of the mind has this peculiarity that it claims to be true, although the fact is also realized that at times *it may be false*. How can we know when a judgment is true or false? What is the test of truth? Some philosophers have contended that the mind simply judges as it does, because it is compelled by some internal law of its own nature which *forces* it to make this or that kind of judgment. That there is some sort of compulsion, is clear enough. We are conscious that we are *not* at liberty to judge *as we please*. Thus, we are compelled to judge that '2 and 2 are 4' and not '5 or 3,' 'man is a sentient being,' 'Napoleon lived,' 'the sun is round,' 'it is winter now,' 'yesterday was Thursday,' 'cows are not fleas,' 'dogs are not mice,' and a million other statements. Absolutely speaking, we can, of course, deny these pronouncements and state their opposites; but in

doing so we immediately become aware of the fact that our judgments are then *false*, and we are doing violence to our better knowledge. Hence, we cannot say that '2 and 2 are not 4,' 'man is not a sentient being,' 'Napoleon never lived,' and so on, with the rest. And even if we found some people who were convinced that '2 and 2 are 5,' while others were equally convinced that '2 and 2 are 4,' we would be constrained to say that both cannot be true, but one judgment is true and the other false. Now, if the truth of a judgment were due to some internal compulsory law of our own mental nature, then both contradictory judgments would have to be true at the same time. But that is obviously ridiculous. If '2 and 2 are 4,' then '2 and 2 are not 5'; and if '2 and 2 are 5,' then '2 and 2 are not 4'; because it is also a law of the mind that *contradictories cannot be true at the same time*. No, the 'truth' of the judgment does not flow from some internal compulsory law of the mind, so that the mind *makes* the judgment true; the mind accepts the truth, because it *recognizes* it as the truth.

What, then, compels the mind to judge as it does? The reason is not at all mysterious. It is this: just as the idea is at bottom a representation of things as they are in themselves, independent of the mind, so the *judgment* is also a *representation of things* as they are in themselves, independent of the mind. When, therefore, the mind compares two ideas with each other and pronounces an agreement or disagreement between them, it *actually* compares two things with each other and judges about their agreement or disagreement among themselves *as they are in reality*. Hence, if a judgment *coincides with*

reality, it is true; if not, it is false. This explains why we are not at liberty to judge as we please. Because in reality things are (or are not) so and so, and the mind has no choice but to represent reality as it actually is.

The world around us, as perceived by our senses, is a reality of experience; we must therefore judge that the 'Sun is round,' 'it is winter now' (if it is' winter), 'yesterday was Thursday' (if yesterday *was* Thursday), 'cows are not fleas,' 'dogs are not mice,' 'men are sentient.' Mathematics is a *reality* of thought, and it tells us that '2 (1+1) and 2 (1+1) are 4 (1+1+1+1)'; we cannot judge any other way. Past events are a reality of *history*, and history assures us that 'Napoleon lived'; the only true judgment we can make, then, is .that 'Napoleon lived.' Even the realm of fancy is a *reality in fancy*; and, in order to make a true judgment from this standpoint, we must judge that 'Witches are evil beings,' because that is the manner in which witches are represented in folklore and poetry.

Agreement of the judgment with reality is therefore the *test of truth*. We verify a judgment by comparing it with the reality it is supposed to represent. Every judgment made by the mind, therefore, implies and presupposes the existence of reality, and this implication of existence is known as the *existential import* of the judgment; this gives it objective value and truth.

PROPOSITIONS

Having examined the nature of the judgment as an act of the mind, we must now study its expression in words. Just

as the ideas are expressed in words which are called 'terms,' so judgments are expressed in sentences which are called 'propositions.'

All propositions are sentences, but not all sentences are propositions. Propositions must contain a *judgment*, and that is not always the case with sentences. Grammar shows this. Consider the following sentences: 'Buddy, can you spare a dime?' 'Please step off my corn!' 'Keep off the grass!' 'Oh, would that the night were over!' These sentences contain a question, a plea, a command, a wish; but they express no straightforward judgment. Consequently they have no place in logic. A *proposition* is defined as a *judgment expressed in a sentence*; or a sentence pronouncing the agreement or disagreement between two ideas.

Three elements enter into the construction of a proposition; *subject*, predicate, and copula. The subject is the term designating the idea (thing) *about* which the pronouncement is made. The predicate is the term designating the idea (thing or attribute) *which* is affirmed or denied of the subject. The copula ('is,' 'is not') is the term expressing the mental act which pronounces the agreement or disagreement between subject and predicate. 'Subject' and 'predicate' are the *matter*, while the 'copula' is the *form* of proposition.

It should be carefully noted, that the 'copula' always expresses the *present* act of the mind in as far as it affirms or denies something at the *very moment of judgment*. Hence, it will always be represented by the present tense of the indicative mood of the verb 'to be,' and it therefore

manifests itself in the words *is* or '*is not*.' Every proposition can be reduced to the verb 'to be,' even if the verb of the sentence refers to some past or future event. 'Man-O'-War won the derby' means 'Man-O'-War *is* the horse that won the derby'; 'President F. D. Roosevelt will lead the country out of the depression' signifies 'President F. D. Roosevelt *is* the man who will lead the country out of the depression'; 'the Communist party did not succeed' is the same as 'The Communist party *is not* the party which succeeded'; 'Sovietism will not prevail' is identical in meaning with 'Sovietism *is not* a government which will prevail.' The meaning of these propositions has in no way been changed by the change of wording and the alteration illustrates the copula hidden in the ordinary sentence. In a similar manner the copula may be hidden in the verb of the present tense; like 'The dog runs,' 'I have a headache,' 'we live,' 'they rave,' 'you err,' 'thou lovest.' Such sentences are easily reduced to logical propositions, as 'The dog *is* running,' 'I *am* having a headache,' 'we *are* living,' 'they *are* raving,' 'you *are* in error,' 'thou *art* in love.'

Language, as we see, has its own way of expressing judgments, different from the direct manner of logic. The logician has the right to change the wording to suit his purposes, provided he retains the *original meaning of the judgment*. The wording, as the logician frames the sentences, may seem unusual and queer, but he is interested in the substance of the thought and not in the niceties of language and in the beauty of poetry. Stripping a sentence of its excess verbiage and arriving at the simple judgment, is not always an easy task; but no matter how

involved a sentence may appear, it is reducible to the simple proposition of a subject, predicate, and copula. Take this sentence: 'Any national emergency, with its concomitant industrial, financial, and social maladjustments, attended by prolonged unemployment and crippling misery for individuals, families, and the government, will eventually give way before the combined initiative and efforts of a sagacious President, a willing Congress, and a confident and cooperating people.' When reduced to its essentials, this lengthy sentence simmers down to the judgment: 'Any emergency will give way,' or, 'Any emergency is something that will not last'; the rest is explanatory. It is precisely because the simple judgment is built up into propositions of such great variety and complexity that the logician must analyze the proposition in all its different types, so as to discover the laws of thought underlying them and then draw up the rules which govern truth and error in each.

SUMMARY OF CHAPTER VI

Truth is not contained in ideas as such, but in the judgment.

1. The *judgment* is an *act of the mind pronouncing the agreement or disagreement of two ideas among themselves*. Three things are required for the making of a judgment: two known ideas, their comparison, and the act of intellect pronouncing their identity or non-identity. Truth and the possibility of an advancement of knowledge lie in this union of two ideas performed by the judgment. The subject-idea and the predicate-idea. are the matter of the judgment; the pronouncement of their agreement or disagreement is the form of the judgment. The mind does *not* make the judgment to be *true*; truth is independent of the mind and lies in the conformity of the judgment to *reality*.

2. The *proposition* is the *judgment expressed in a sentence*. Every proposition consists of a *subject, a predicate, and the copula*; subject and predicate are the *matter*, and the copula is the *form* of the proposition. Since the copula expresses the present act of the mind in its judgment, it is always expressed in the present tense of the indicative mood of the verb 'to be,' even if the sentence refers to past or future events.

Even the most involved sentences can be reduced to a subject, a predicate, and a copula.

Chapter 7

GENERAL TYPES OF PROPOSITIONS

IT IS THE PURPOSE OF ALL THINKING TO DISCOVER AND RECOGNIZE truth, and truth lies ultimately in the judgment. Many truths are unimportant, like 'It snowed last night'; but scientific truths are of great value, because they influence the material and spiritual welfare of mankind in all its phases. Now, all the truths of science are formulated into laws, and this formulation is done by expressing these laws in judgments and propositions. Since, however, these laws are discovered only after lengthy and arduous investigations, it is obvious that a host of ordinary judgments and propositions will have to precede the final judgment and proposition which contains the law. Not only must this final proposition be true, but every preceding proposition leading up to it must also be true. The scientist and philosopher must, therefore, understand the import and value of every *type* of proposition which can possibly be used by the mind in investigating the truth and in formulating the laws. Otherwise error may creep in surreptitiously and vitiate his final conclusions.

There are different types of propositions; some are general and some are *special types*. We must first consider

the *general* types, because they affect all propositions and are based on *characteristics* which may be found in all special types. These general characteristics of propositions are 'quality,' 'quantity,' and 'relation.'

QUALITY OF PROPOSITIONS

The *quality* of a proposition affects the *copula* and makes the proposition either *affirmative* or *negative*. The predicate is either affirmed or denied of the subject. 'Ants *are* insects,' 'a whale *is* a mammal,' 'soldiers *are* fighters': here the copula affirms the predicate of the subject. 'Ants *are not* vertebrates,' 'a whale *is not* a fish,' 'soldiers *are not* sailors': here the copula denies the predicate of the subject. Sometimes a sentence will have two copulas, one in the main proposition, the other in a qualifying clause. Here are two examples: 'A man who *is* sick *is not* healthy' and 'A man who *is not* sick *is* healthy.' In both cases the clause affects the subject 'a man.' Are these propositions affirmative or negative? If the copula of the *main* proposition is negative, it is a negative sentence; if it is affirmative, it is an affirmative sentence: hence, the first sentence is negative, the second is affirmative. The *meaning* shows this clearly: 'A sick man is not healthy' and 'a not-sick man is healthy.' In all doubtful cases we must look to the meaning of the sentence before we decide, and the meaning can usually be discovered by some slight change of the words.

Since the predicate is affirmed or denied of the subject, how does this affect the *comprehension* and *extension* of the *predicate*? Do comprehension and extension remain the

same or are they changed in any way? This is a very important question, with a vital bearing on the validity of argumentations (as will be seen later); the relation of predicate to subject from this standpoint, therefore, should be well understood. Here are the rules:

In an *affirmative* proposition the *predicate* is always affirmed of its subject according to the *whole of its comprehension* and according to a *part of its extension*.

In a *negative* proposition the predicate is always denied of its subject according to only a *part of its comprehension* and according to the *whole of its extension*.

The nature of the judgment proves these rules. If I affirm, for instance, that 'Man is an animal,' just what do I mean to assert by applying the predicate 'animal' to the subject 'man'? I assert an *identity* between the two ideas. Consequently, the comprehension of the idea 'animal' must be found in the idea 'man.' And that is really the case. 'Man' is a 'rational, sentient, living, bodily substance,' while 'animal' is a 'sentient, living, bodily substance'; plainly, then, I am applying the *whole* of the *comprehension* of 'animal' to the subject 'man,' because the definition of 'animal' is found to be *contained* in the definition of man.' On the other hand, I do not mean to assert by this proposition that the whole of the extension of 'animal' applies to 'man,' because that would mean that 'man' would fill out the whole extension of 'animal' and there would then be no other beings besides 'man' in this extension. But that is obviously false. Other beings besides 'man' belong to the extension of 'animal,' namely 'brutes.' In an affirmative proposition, therefore, I merely intend to assert that the subject forms a *part*

(together with others) of the *extension* of the predicate. In other words, in an affirmative sentence the predicate is taken only as a particular term, i.e., it is a universal term taken *partly* and *indeterminately* with regard to its extension. This is the reason why we can truthfully say that 'Every man is an animal,' but we cannot turn the sentence around and say that 'Every animal is a man.' This would only be the case when the predicate is the *definition* of the subject, as 'Man is a rational animal,' because 'man' and 'rational animal' are the same thing in different words.

A brief consideration will also prove the truth of the second rule. If I state 'Snails are not vertebrates,' I deny the identity between the predicate 'vertebrates' and the subject 'snails.' This means that the *comprehension* of 'vertebrates' contains something which is not found in the comprehension of 'snails.' And rightly so. Both are 'animals'; but 'vertebrates' are 'animals *with a backbone*,' while 'snails' are 'animals *with no backbone*.' But by denying that the *whole* of the comprehension of 'vertebrates' is found in 'snails,' I realize that *part* of the comprehension may be found in the subject; as a matter of fact, the element 'animal,' found in the comprehension of 'vertebrates,' is also found in the comprehension of 'snails.' Hence, in a negative sentence the *whole* of the comprehension of the predicate *never* applies to the subject, but a *part* of the comprehension does. The second part of this rule is also true: the predicate is always taken according to the *whole* of its extension and *denied* of the subject. Thus, when I state that 'Snails are not vertebrates,' I intend to assert that 'snails' do not belong at all to the

class of 'vertebrates'; they stand entirely outside this class, because every one belonging to the class of 'vertebrates' has a 'backbone,' which is something which *no* 'snail' has. In a negative sentence, therefore, the predicate is always taken according to its whole extension as a *universal* and then *denied* of the subject. Since both, subject and predicate, belong to totally different classes, neither belongs to the class of the other; in consequence of this I can take the sentence 'Snails are not vertebrates' and turn it around with equal truth and say that 'Vertebrates are not snails.'

And thus the two rules of affirmative and negative propositions are verified. So much for the quality of propositions.

QUANTITY OF PROPOSITIONS

The *quantity* of a proposition affects the *whole judgment as a judgment*; it expresses the number of *individuals* to whom the judgment or proposition applies. Since the predicate is referred to the subject, the proposition will be true of all the individuals contained in the extension of the *subject*. From the standpoint of quantity, then, propositions will be *universal, particular, singular, or collective*, whichever way the subject is taken.

A proposition will be *universal*, if the subject is a universal term applied *distributively* to each and all of the class. 'All' and 'every,' prefixed to the subject, indicate the universality of the proposition: 'All male mosquitoes bite,' 'every cat purrs.' There can never be any doubt about the

term 'every'; but the term 'all' may be ambiguous, because it may mean 'all taken collectively' and then it would not apply to each and every member of the class. If I say 'All members of the society were present at the meeting,' I use the term 'all' distributively, because I mean '*Every* member was present'; but if I say 'All the prisoners filled the cellblock,' I use the term 'all' collectively, since I cannot say that '*Every* prisoner filled the cellblock.' Here again we must look to the meaning. The universal negative proposition is expressed by prefixing 'no' to the subject, as 'No airplanes can travel as far as dirigibles,' 'no swans are red,' 'no man is an angel,' 'no square is round.'

One must remember, however, that there are different *grades* of universality as applied to propositions. A proposition will be *metaphysically* universal, when it applies to each and every member of the class with an absolute necessity, so that there can be *no exception* under any circumstances. Here are some instances of propositions which have metaphysical universality: 'Man is a rational animal,' 'all circles are round,' 'two and two are four,' 'no squares have five sides,' etc. An exception here would involve a contradiction in the very idea. A proposition will be *physically* universal, when it applies to each and all according to some *natural law*; an exception could be made by divine power only. Examples: 'Every animal must die,' 'no dead man can be brought back to life,' 'matter cannot penetrate matter' 'all water at sea level freezes at +32° F.,' 'all bodies are attracted by the force of gravitation.' A proposition will be *morally* universal, when it applies to all individuals of a class according to *general custom*; there

may be exceptions in individual cases. Such are the propositions 'All parents love their children,' 'gamblers are free spenders,' 'all children love sweets,' 'all Scotsmen are thrifty,' 'no criminals are trustworthy.'

A proposition is *particular*, when the subject is a *universal* term used *partly* and *indeterminately*. It is indicated by the term 'some' or 'not all,' attached to the subject. As 'Some dogs are very affectionate,' 'not all men are learned,' 'some houses are old,' 'some soldiers are cowards.' Words are often deceiving. The statement 'All men are not drunkards' seems on the face of it to be universal. If it were universal, it would mean 'No men are drunkards,' but this is certainly not the sense intended; the meaning is evidently 'Not all men are drunkards,' and that is the same as saying 'Some men are not drunkards,' which makes it a particular proposition.

A proposition is *singular*, when the subject applies to a *single individual only*. Such are the statements 'St. Paul was an Apostle,' 'this dog is lame,' 'that man is not tall,' 'the present Pope is an Italian.' Singular propositions have the same value as universal propositions and are treated the same way, because the subject is taken according to the *whole* of its extension, which in this case is one.

A proposition is *collective*, when the subject is a collective term, applying to all taken *together as a class*, but not to the individuals composing the class. We have collective propositions when we say 'The Germans were defeated in the World War,' 'the herd scattered,' 'all his books filled half a shelf'; we mean 'the Germans' as a nation, the 'herd' as a group, 'all his books' as a set. Since a

collective term represents many considered as one, it is taken according to the whole of its extension and it, too, is treated as a universal.

There is one more proposition, considered from the viewpoint of quantity, which we must take into account: it is the *indefinite* proposition, which has no definite sign of quantity attached to the subject. 'Children are petulant,' 'woman is fickle,' 'youth is flippant,' 'a car is expensive,' 'cats are a nuisance,' 'man is an animal,' 'athletes are strong-bodied'; such and similar propositions indicate no definite quantity. They evidently mean some or 'all' and are either particular or universal propositions. The sense of the statement or the context in which they are used must give us the exact quantity.

Since singular and collective propositions are equivalent to universal propositions, all judgments have the value of either *universal* or *particular* propositions. And as all propositions will be either *affirmative* or *negative*, we arrive at the following results, as far as quality and quantity of propositions are concerned: the universal affirmative, the universal negative; the particular affirmative, the particular negative. Logicians express them in a sort of logical shorthand with the letters A,E,I,O. They take the Latin words 'AffIrmo' and 'nEgO.' The vowel 'A' stands for the universal affirmative proposition; the vowel 'I' stands for the particular affirmative; the vowel 'E' stands for the universal negative proposition; the vowel 'O' stands for the particular negative. In a similar manner 'S' represents 'subject' and 'P' represents 'predicate.' The symbol for a universal affirmative proposition is therefore SaP; for a

particular affirmative, SiP; for a universal negative, SeP; for a particular negative, SoP. This gives us the following scheme:

Universal affirmative – (A)... SaP...Every man is mortal.

Universal negative --- (E)... SeP... No man is an angel.

Particular affirmative – (I)... SiP... Some men are kind.

Particular negative --- (O) . . SoP... Some men are not learned.

If the logician wishes to discuss a universal affirmative proposition, he may either quote a sentence like 'Every man is mortal' or use the symbol 'SaP'; a universal negative proposition will be either something like 'No man is an angel' or simply 'SeP'; a particular affirmative proposition can be illustrated either by a sentence like 'Some men are kind' or by 'SiP'; while a particular negative proposition may appear in either of two ways, as a statement like 'Some men are not learned' or as the symbol 'SoP.' Sentences, of course, are clearer, because they have a direct meaning; but the symbols are briefer and have this advantage that they represent any kind of sentence. For instance, 'Every man is mortal' is merely an *example* of a universal affirmative proposition, having but *one* meaning; but 'SaP' would stand for *every conceivable* universal affirmative proposition, and therefore represents them *all*. We will use both, sentences and symbols, whichever is most convenient

for the purpose; a clear understanding of the symbols is therefore a practical requirement.

RELATION OF PROPOSITIONS

The third general division of propositions is based on the *relation* between subject and predicate. Of course, the subject and predicate of every proposition have the relation of agreement or disagreement among themselves; but this relation between the two may be either *necessary or contingent*. By this we mean that the connection between both terms is either *absolutely necessary and unchangeable* or it is *contingent and changeable*. A few examples will show the difference. Consider these statements: 'Man is rational,' 'man is an animal,' 'two and two are four,' 'a square is a quadrangle,' 'the angles of a triangle are equal to two right angles,' 'the whole is greater than its part,' 'the square of the hypotenuse of a right-angled triangle is equal to the sum of the squares on the other two sides,' 'living beings are substances,' 'man is capable of speech.' And now consider these statements: 'Cows are cloven-hoofed,' 'the Germans were defeated in the World War,' 'some dogs are vicious,' 'some men are learned,' 'iron is heavy,' 'water boils at +212° F.,' 'the Hawaiian Islands belong to the United States,' 'France is a republic,' 'gold is precious.' It takes but a glance to perceive the great difference between these two sets of statements. We can know the truth of this last set *only by experience*; we perceive that the predicate actually belongs to the subject, but *not necessarily*. In the former set we know that the predicate actually belongs to the

subject, and we also perceive that it must belong to it, *independent of experience*; the relation between the two terms is *necessary* and *unchangeable* under all circumstances. Why this difference?

The difference lies in the fact that the first set of propositions involves something *essential*, while the second set contains only *accidental* attributes. By 'essential' we here mean the whole or part of the essence (species, genus, differentia) or something *necessarily resulting* from the essence (property). In other words, in the necessary (essential) propositions the relation between subject and predicate is such that the one is the species or genus or differentia or property of the other; the one is contained in the *comprehension* of the other. Hence, an *analysis* of the one will always reveal the other as contained in it, without the need of appealing to experience to prove its truth. Take the first example: 'Man is rational.' What is 'man'? 'Man' is a substance which is bodily, living, sentient, *rational*.' Here we see how the analysis of the subject 'man' reveals the predicate 'rational'; the predicate is contained in the very *comprehension* of the subject, because 'rational' is the differentia of 'man.' Take the example: 'A square is a quadrangle.' A 'quadrangle' is a 'plane figure with *four sides*,' and a 'square' is a 'plane figure having *four equal sides* with four right angles.' A 'quadrangle,' therefore, is the genus of the 'square' and is contained in its comprehension; the analysis of the 'square' reveals the predicate 'quadrangle' as part of the comprehension and essence of the subject 'square.' Now take the example: 'Man is capable of speech.' Here the case is different;

analyzing 'man,' the predicate 'capable of speech' is not contained in the comprehension of the subject 'man,' who is defined as a 'rational, sentient, living, bodily substance.' But let us *analyze the predicate*. By 'speech' we understand 'vocal sounds which express ideas.' Now, only an 'animal' is capable of 'vocal sounds,' and only a 'rational being' can 'express ideas.' But a 'rational animal' is 'man.' Here, then, by analyzing the predicate I find the subject *contained* in the *comprehension of the predicate*.

In the second set, neither the subject is contained in the comprehension of the predicate nor the predicate in the comprehension of the subject. The relation between the two is one of *fact only*, and this fact is a *contingent* fact, i.e., it is *actually* so, but it *could be otherwise*. That the predicate actually belongs to the subject is true; the truth of the statement, however, cannot be known and shown from an analysis of subject and predicate, but by an appeal to fact and experience. Take, for example, the statement 'The Germans were defeated in the 'World War.' This is true; but it is *not necessarily true*; it simply happened to be that way, and it could have been different. The idea of a 'defeat in the World War' is not contained in any way in the comprehension of 'Germans' as 'Germans,' and therefore an analysis of the idea 'Germans' will never reveal the idea 'were defeated in the World War.' Only an appeal to experience and fact can prove the truth of the statement. So, too, in the statement 'Some men are learned' the attribute 'learned' does not belong to the comprehension of 'man,' otherwise *all* 'men' would have to be 'learned,' since all men have the same comprehension. That 'Some men are

learned' is a *contingent fact*, and 'learnedness' is a mere *accident* which may or may not be found in 'man.' In all such instances, therefore, we have a synthesis of a subject and an *accidental* (contingent) *attribute*; and an accident, of course, is never necessary. This is the reason why these propositions are called *synthetic* while the others are styled analytic.

Where the relation of subject and predicate is necessary and unchangeable, we have an *analytic* proposition; where this relation is contingent and changeable, we have a *synthetic* proposition. Analytic propositions are also called 'necessary,' 'essential,' '*a priori*'; and the synthetic propositions go also by the name 'contingent,' 'accidental,' '*a posteriori*.'

The terms '*a priori*' and '*a posteriori*' need explanation. As the words indicate, '*a priori*' refers to something that 'comes first,' and '*a posteriori*' to something that 'comes after.' Knowledge is said to be '*a priori*' when it is obtained by reasoning from the whole to the parts, from the cause to the effect, because the 'whole' is 'prior' to the 'parts' and the 'cause' is prior to the 'effect.' When this knowledge is obtained by reasoning from the parts to the whole, from the effect to the cause, it is '*a posteriori*,' because 'parts' and 'effects' are posterior to (later than) the 'whole' and the 'cause.' Now, in an *analytic* proposition the mere analysis (unfolding) of the subject or predicate as a 'whole' or 'cause' will reveal the other term as a 'part' or 'effect,' and such a proposition will therefore be '*a priori*.' In the *synthetic* proposition the essence of the subject or predicate does not contain the other, and an analysis

(unfolding) of the one will not disclose the presence of the other; in this case, knowledge is obtained by observation and experience, but not from an examination of the essence of subject and predicate, and such knowledge is therefore '*a posteriori*.' Hence, every analytic judgment (and proposition) is '*a priori*,' while every synthetic judgment (and proposition) is '*a posteriori*.' Therefore:

An *analytic* (or necessary, essential, *a priori*) proposition is one in which either the *predicate is contained in the comprehension of the subject, or the subject is contained in the comprehension of the predicate*.

A *synthetic* (or contingent, accidental, *a posteriori*) proposition is one in which *neither the subject nor the predicate is contained in the comprehension of the other*.

The phrase 'or the subject is contained in the comprehension of the predicate,' stated in the definition of the *analytic* proposition, should be carefully noted. It is important. When should a judgment or proposition be called *analytic*? Evidently, when the relation between subject and predicate is necessary and when this relation can be discovered by a mere *analysis* of subject and predicate. It should, therefore, make no difference whether the predicate is contained in the comprehension of the subject, or the subject is contained in the comprehension of the predicate, as long as an *analysis* of the one reveals the presence of the other. This is plain reasoning, and it is based on the very idea of 'analysis.' But now, in cases where the predicate represents a '*property*' of the subject, the predicate will not be found in the comprehension of the

subject, but the *subject* will be found in the *comprehension of the predicate*.

We had an example of this relation in the proposition 'Man is capable of speech.' Since 'speech' means 'vocal sounds which express ideas,' a being 'capable of speech' must have an '*animal*' nature, since only an 'animal' can emit 'vocal sounds'; and since only a '*rational*' being can 'express ideas,' a being that is 'capable of speech' must be a 'rational animal,' which is precisely the definition of 'man.' Here, then, we have a *necessary* relation between subject and predicate; but in this case the predicate is not contained in the comprehension of the subject, but the subject, as the *analysis shows*, is contained in the comprehension of the predicate. The proposition 'Man is capable of speech' must therefore also be classed as a true analytic proposition.

Another example. The simple proposition '2 and 3 are 5' contains a necessary relation between the subject '2 and 3' and the predicate '5.' No amount of analysis, though, will disclose the presence of '5' in the subject '2 and 3.' Nevertheless, this is not a synthetic, but an *analytic* judgment. Here the predicate is not contained in the comprehension of the subject, but an analysis will reveal the fact that the subject '2 and 3' is contained in the comprehension of the *predicate*. What is '5'? It is '1+1+1+1+1' What is '2'? It is '1+1' And '3'? It is '1+1+1' Therefore, the subject '2 and 3' is identical with '1+1' and '1+1+1' and this is found in the predicate '5' which as '1+1+1+1+1' The truth of the judgment is disclosed by an analysis of the predicate in its relation to the subject, and

this makes the proposition analytic. This will always be the case when the predicate is a 'property' of the subject, since a 'property' does not belong to the definition of the subject and still results necessarily from the essence.

It is well to bear this in mind, since most modern philosophers, following the noted German philosopher, Emmanuel Kant (1724—1804), define these two types of propositions differently. They define the analytic proposition as 'one in which the predicate is contained in the definition of the subject'; and the synthetic proposition as 'one in which the predicate is not contained in the definition of the subject.' This definition is entirely too limited. According to this explanation, only those propositions can be styled analytic in which the predicate is found in the subject. This is an arbitrary restriction. Surely, any proposition whose necessary truth can be shown by a mere analysis of the subject and predicate should be called analytic, whether the predicate be contained in the subject or the subject in the predicate. The latter has just as much right to be called an analytic proposition as the other. Now, as has just been shown, we can prove the necessary truth of propositions based on 'property by an *analysis* of subject and predicate, since in this case the subject is contained in the comprehension of the predicate. Hence, these propositions are genuinely *analytic*, and are not 'synthetic a priori,' even though the predicate here is not contained in the definition of the subject. The attitude here of the Kantian philosophers is therefore incorrect and unwarranted.

These, then, are the general types of proposition. 'Quality' gives us affirmative and negative propositions;

'quantity' gives us universal, particular, singular, collective, and indefinite propositions; the necessary or contingent 'relation' between subject and predicate gives us analytic and synthetic propositions. The general characteristics manifested in these types affect all the special types. These special types will also have to be studied, so that the logician may understand their full value and import and discover the truth or falsity hidden under the vesture of language.

SUMMARY OF CHAPTER VII

Truth and falsity are found in the judgment and proposition; hence, a knowledge of the various types of propositions is necessary. There are general and special types. The general types are based on the *quality, quantity, and the relation* of subject and predicate found in the proposition.

1. From the standpoint of quality a proposition is either *affirmative* or *negative*. In an affirmative proposition the predicate is always used according to the *whole* of its comprehension and a *part* of its *extension*, it is, therefore, always a *particular* term. In a *negative* proposition the *predicate* is always used according to a *part* of its *comprehension* and the *whole* of its *extension*; it is, therefore, always a *universal* term.

2. The quantity of a proposition affects the whole proposition as such and expresses the *number of individuals* to whom the judgment applies. This is shown by the *extension* of the *subject*. Depending on this, propositions will be universal, particular, singular, collective, or indefinite. These can all be reduced to the value of a universal or *particular* proposition. Symbols: A, E, I, O.

3. From the standpoint of the relation between subject and predicate, propositions will be either *necessary* or *contingent*. When the relation is in a *necessary* matter, the *subject* is always contained in the *comprehension* of the predicate, or vice versa; hence, an analysis of the one will reveal the other and thereby reveal the truth of the

proposition. But when this relation is in a *contingent* matter, *neither subject nor predicate* is contained in the *comprehension* of the other, and an analysis of the one will *not* reveal the other; since this relation is based on a *contingent fact*, we can prove the truth of the proposition only by *experience*. The necessary proposition is, therefore, analytic, while the contingent proposition is *synthetic*; the former is also called 'a priori' and the latter 'a posteriori.'

Chapter 8

SPECIAL TYPES OF PROPOSITIONS

LANGUAGE IS THE VESTURE OF THOUGHT AND, LIKE THE CLOTHING on a body, it both reveals and hides the truth underneath. The human mind loves to give utterance to its ideas and judgments in a variety of ways. Language, however, is at best only an imperfect medium of expression, incapable of giving adequate shape to all the subtleties and nuances of meaning involved in the process of thinking. What is a simple act of the mind must be expressed in a number of words, and the result is often far from satisfactory. It is a long road from the twaddle of a child and the prattle of a savage to the ethereal flights of a master poet and the profound depths of a world-plumbing philosopher; yet all language in whatever form strives for the self-same goal — to convey thought and truth from mind to mind. This is the function of language. It is the imperfection of language which forces the mind to weave it into intricate textures of words, so that at times the truth is almost more hidden than revealed. It makes the task of the philosopher doubly difficult. The logician, then, must resolve these complicated sentences into simpler forms, so as to uncover the hidden truth of their meaning. And since truth lies ultimately in the

judgment and proposition, it becomes the duty of logic to classify and analyze the various *types of propositions*.

There are *two main divisions* of propositions, the *single* and the *multiple*, the *categorical* and the *hypothetical*.

The *single* proposition is one that consists of one subject and one predicate: 'Man is a rational animal,' 'air is a gas,' 'the street is paved.' The *multiple* proposition is one that consists of two or more propositions united into one: 'Jack and Jill went up the hill,' 'Peter was an apostle and a martyr,' 'if it rains, you need not sprinkle the lawn,' 'the earth is white, because it snowed.' A *categorical* proposition is one in which a predicate is attributed to its subject outright, without restriction or condition: 'Air is a gas,' 'she is beautiful but dumb,' 'Peter and Paul were martyrs,' 'he is as generous as he is wealthy.' A *hypothetical* proposition is one which does not attribute a predicate to its subject directly, but asserts the dependence of one judgment on another: 'If it rains, you need not sprinkle the lawn,' 'a body is either in motion or at rest,' 'a religion cannot be true and false at the same time.'

Examining the relationship between these two main groups, one will notice at a glance that they are not exclusive of each other. The single and multiple propositions exclude each other; and the categorical and hypothetical exclude each other. But while the single propositions are always categorical and the hypothetical propositions are always multiple, the categorical propositions may be either single or multiple; a comparison of the examples shows this plainly, but it will become clearer as we investigate the different kinds of propositions contained in these groups.

For the sake of convenience we will divide all propositions into *categorical* and *hypothetical*, subdividing the categoricals into *single* and *multiple*. In this way the entire field will be covered.

SINGLE CATEGORICAL PROPOSITIONS

The *categorical proposition*, as has been stated, makes a direct assertion (hence it is also called *assertoric*) of agreement or disagreement between subject and predicate.

The *single* categorical contains but a *single sentence* in its construction — one subject, one predicate, and the copula if these elements of the sentence are *without* any qualification or composition, it is a *simple* categorical, as ‘Man is rational,’ ‘air is a gas.’ Its very simplicity precludes any difficulty, and nothing further need be said of this type. But if a *qualification* or *composition* enters into the subject or predicate or copula, we have a *composite* single categorical proposition. There are two kinds of these composite propositions, the complex and the modal propositions.

The *complex* proposition is a composite sentence in which both the subject and the predicate or either one is a *complex term*. ‘Man’ is a simple or in-complex term; but ‘learned man,’ ‘good man,’ ‘mortal man,’ ‘intelligent man’ are complex terms. Any such term used as subject or predicate, or any verb expressing past or future time used as a predicate, makes the sentence a complex proposition. For instance, ‘Man is a rational animal,’ ‘police dogs are faithful companions,’ ‘the heavy rain washed the soil down

the hill,' 'the heat of the sun will make the flowers bloom in the springtime,' 'some warm-blooded animals do not thrive in the arctic zone.' In all these instances there is but one judgment, with one subject and one predicate, but the one or the other is a qualified (complex) term. Each sentence, of course, presupposes *former* judgments. Thus, the complex term 'rational animal' implies the former judgment that 'some animals are rational'; but the proposition 'man is a rational animal' represents a *present* judgment which is single but complex. Some qualifying words are *explicative*: they qualify *every* individual belonging to the extension of the qualified term; such is the term 'rational' in the sentence 'rational man is mortal,' and the term 'speeding' in the sentence 'the speeding cars raced around the track.' Others are *restrictive*; they reduce the qualified term to a *portion* of its extension; as the term 'wingless' in the statement 'wingless birds are rare,' and the term 'better' in the statement 'the better cars are expensive.' In judging the truth of complex propositions, not only must the main judgment be true, but the former judgment involved in the complex term must also be true. Thus, in the proposition 'mortal man is intelligent,' it must be true that 'man is intelligent' and that 'man is mortal.'

The *modal* proposition is a composite single sentence in which the *copula* is so *modified* as to express the *manner* (mode) in which the predicate belongs to the subject. The qualification does not affect the subject or predicate, but the copula itself; namely, it states whether the *objective connection* between subject and predicate, expressed by the *copula*, is necessary, impossible, possible, or contingent.

There are, therefore, four such modes, each of which produces a different kind of proposition.

The *necessary* modal proposition states that the predicate belongs to the subject, and *must* belong to it; for instance, 'Man is necessarily an animal,' 'a circle must be round,' 'that 2 and 5 are 7, is necessary.' The *impossible* proposition states that the predicate does not and cannot belong to the subject; as 'It is impossible that God be unjust,' 'the animal soul cannot be spiritual.' The *possible* proposition enunciates the fact that the predicate is *not actually* found in the subject, but it *might* be; such are 'This car can attain a speed of 75 miles an hour,' 'with his defective heart a sudden death is possible.' The *contingent* proposition states that the predicate *actually belongs* to the subject, but it need not; as, 'It is not necessary that this eagle keep on flying,' 'these students need not be lazy.' Since the peculiarity of the modal proposition lies precisely in its 'mode,' the truth of the judgment depends mainly on the truth of this 'mode? Like the complex proposition, the modal proposition *presupposes* a former judgment; thus the statement 'It is necessary that God be just' implies the former judgment that 'God is just.'

MULTIPLE CATEGORICAL PROPOSITIONS

The complex and modal propositions represent the two types of *single* categoricals. *Multiple* categoricals are propositions which contain *two or more sentences in their very construction*. Of these some are overtly, while others are covertly, multiple; the latter are called 'exponibles.'

The *overtly multiple* categoricals are *plainly composed of two or more propositions*. They are five in number: copulative, adversative, relative, causal, and comparative.

The *copulative* proposition has two or more subjects, or two or more predicates; or two or more subjects and predicates, combined into a grammatical unity. Examples: 'Eagles and sparrows are birds'; 'the man slipped and fell and broke his arm'; 'Alfred E. Smith and Franklin D. Roosevelt were governors of New York State and candidates for the presidency.' Each of these sentences can be resolved into as many single propositions as there are different subjects and predicates; thus, 'Eagles are birds' and 'Sparrows are birds.' Such sentences, of course, can also be negative, as 'Neither his sisters nor his brothers spoke to him.' The truth of copulative categoricals depends upon the truth of all the single sentences which compose the multiple proposition.

The *adversative* (or *discretive*) proposition consists of two propositions united in opposition to each other by conjunctions like 'but,' 'although,' 'yet.' Examples: 'The plaintiff lost his money, but not his honor, in the lawsuit'; 'the father was lenient, although the child was stubborn'; 'the depression harmed his business, yet he was not despondent.' To be true, each sentence must be true.

The *relative* proposition expresses a relationship of time or place between two sentences. Examples: 'After going to the store, he went home'; 'before lighting a cigarette, he began to talk.' Such propositions are true, if the single statements and the relation of their sequence is true.

The *causal* proposition combines two statements together in such a way that the 'one is given as the reason or cause of the other; the words 'for' or 'because' show the type. Examples: 'The times are hard, for people have no money'; 'the soul is immortal, because it is immaterial'; 'the man is contented, because he is a millionaire.' The truth of the causal proposition depends upon the truth of each categorical proposition contained in it and upon the causal connection declared to exist between them.

The *comparative* proposition compares the relation between a subject and predicate with the same relation between another subject and predicate, and expresses the degree of this relationship as being either less or equal or greater. Examples will clarify this somewhat complicated definition: 'Napoleon was a greater general than Caesar'; 'as you live, so you die'; 'Hoover was less active than Roosevelt.' Three statements are contained in each of these propositions: the two simple statements, for instance, that 'The quality of Napoleon's generalship was great, and 'The quality of Caesar's generalship was great'; and the comparative degree of this quality, namely, 'The quality of Napoleon's generalship was the greater of the two.' The truth of a comparative proposition depends on the truth of the two separate sentences and on the truth of the degree mentioned as existing between them.

THESE OVERTLY MULTIPLE CATEGORICAL PROPOSITIONS DO NOT present any great difficulties. The *covertly multiple* categoricals, however, have the *appearance of single*

propositions, although they are really multiple. Their composition lies concealed in some word and needs an exposition to show the multiple character; hence, they are styled '*exponibles*,' and the sentences into which the general proposition can be resolved are called the 'exponents.' The *exponible* propositions, as far as their truth is concerned, will be true, if the 'exponents' and the logical connection between them are true; if any of these parts are false, the entire proposition is false. The '*exponibles*' are five in number: exclusive, exceptive, reduplicative, specificative, and inceptive-desitive propositions.

The *exclusive* proposition contains some particle of speech like 'only,' 'alone,' 'solely,' 'none but,' which indicates the exclusion of any other predicate from this subject or any other subject from this predicate. Examples: 'Only God can make a tree'; 'Cicero was only an orator'; 'not only the brute is not rational.' The affirmative exclusive *exponible* will be resolved by means of a copulative proposition, in which one sentence is affirmative and the other negative; thus, the proposition 'Only God can make a tree' will become 'God can make a tree and all others cannot make a tree.' The negative exclusive *exponible* will be resolved into two negative exponents; the sentence 'Not only the brute is not rational' will become 'The brute is not rational and some other creature is also not rational.'

The *exceptive* *exponible* proposition contains a particle of speech like 'except' or 'save,' to indicate that a portion of the extension of the predicate does not apply to the subject, or vice versa. Examples: 'All persons except one were killed

in the wreck'; 'all students save three were not indolent.' The resolution of such exponibles should be easy: 'One person was not killed in the wreck, and all others were killed.'

The *reduplicative* and *specificative* propositions are alike in this that they contain an expression which duplicates the subject or predicate, giving them special emphasis, like 'as such,' 'as a.' The difference between the two types of propositions is this: the reduplicative implies the reason or cause for the connection between subject and predicate, while the specificative merely implies the time element or condition of this connection. An example will illustrate the point. If I state that 'Man as a man, is endowed with free will,' I intend to say that 'Man, because he is man, is endowed with free will'; similarly, if I state that 'Christ, as God, is eternal, but Christ, as man, is mortal.' These are reduplicative propositions. But when I say that 'John, as a student at college, participated in athletics,' or that 'The doctor, as a physician, was a very congenial man,' my statements are specificative, because athletics has nothing to do with student because he is a student, and congeniality is not a quality of a physician because he is a physician. Were I to state, however, that 'John was a good student, as such,' meaning that he studied as a student should, or that 'The doctor, as a physician, was a good diagnostician,' my statements would be reduplicative. Such propositions are true, when both the plain statement and the reduplicative or specificative sub-statement are correct.

The *inceptive* and *desitive* propositions include a declaration of time when something begins (inceptive) or

ends (desitive). Examples: The statement that 'The last depression began with the financial crash in Wall Street in 1929' is an inceptive proposition; 'The World War ceased with the armistice on November 11, 1918,' is a desitive proposition. These kinds of sentences are resolved as follows: 'There was no depression before the financial crash in Wall Street in 1929, and there was a depression after this financial crash'; 'the World War was fought before the Armistice of November 11, 1918, and the World War was fought no longer after this armistice.' Truth depends, of course, upon both exponents.

These, then, are the various types of *categorical* propositions, whether *single* or *multiple*. The categoricals always make a clean-cut assertion. In the *hypothetical* propositions, however, the pattern, though fundamentally the same, is somewhat different in thought and structure.

HYPOTHETICAL PROPOSITIONS

The *hypothetical* proposition differs from the categorical (*assertoric*) in this, that it does not declare an unqualified affirmation or denial, but expresses the *dependence of one affirmation or denial on another affirmation or denial*. It manifests itself in three distinct types: the conditional, the disjunctive, and the conjunctive.

The *conditional* proposition expresses a relation in virtue of which one proposition necessarily flows from the other. These are the so-called 'if' propositions; the one containing the 'if' is styled the 'condition' or '*antecedent*,' while the other is the 'conditioned' or '*consequent*.' Examples: 'If

there is no God, the world cannot exist'; 'if the barometer falls, there will be a storm'; 'if animals can think, they are rational'; 'if the soul cannot die, it is immortal.' It will be noted that there is a strict relation expressed in such statements; the 'antecedent' must be true, before the 'consequent' can follow. The truth of this type does *not* depend on the truth of the two statements taken individually and separately, but on the *relation* between them. Take the first example as an illustration. I do not mean to assert that 'God does not exist' or 'The world cannot exist'; what I mean to affirm is that 'The existence of the world depends on the existence of God' as an effect on its cause, and therefore '*If* God does not exist, the world cannot exist.' Similarly, in the second example, I do not intend to assert that 'The barometer is falling' or that 'A storm is coming,' but that 'The coming of the storm is dependent on low atmospheric pressure which is indicated by the falling of the mercury in the barometer.' It is the *dependence* of the one on the other that is affirmed or denied, and on the truth of this dependence rests the truth of the whole statement. The conditional proposition is also called *connex* or (in a special sense) *hypothetical*.

The *disjunctive* proposition is an 'either-or' statement, indicating that the implied judgments cannot be true together nor false together, but one must be true and the other (or others) false. Examples: 'Either the sun or the earth moves in an orbit'; 'man is the result either of creation or of evolution'; 'a body is either in motion or at rest'; 'all energy is either kinetic or potential.' It stands to reason that a *strict or proper* disjunction must be such that

the parts can neither be true nor false together. Hence, it would be an invalid disjunction to state 'He is either walking or sitting,' because he may be 'standing' or 'lying down'; or to state that 'He is either talking or walking or eating,' because he may do all three things at the same time. Sometimes, however, the disjunctive proposition is taken in a *wider* sense, and the meaning of this *improper* disjunction is then 'at least one, but possibly some or all of the parts'; such is the statement 'Either St. Peter or St. Paul or St. John died at Rome.' In this wider sense, all are not allowed to be false, but all may be true; as a matter of fact, in the example just given, SS. Peter and Paul died at Rome, while St. John did not. Corresponding to this double use of the disjunctive proposition, one must judge the truth of such statements.

A *conjunctive* proposition expresses a judgment that two alternative assumptions are not or cannot be true simultaneously. Examples: 'A body cannot be in motion and at rest at the same time'; 'rain and sunshine cannot occur at the same time'; 'a student cannot be diligent and indolent at the same time'; 'no one can be a sinner and a saint at the same time.' For the truth of such a proposition it is necessary that they are really irreconcilable 'at the same time'; if one can show that they may be present together, this would prove the statement to be false. Taking the second example, one may rightly object that 'Occasionally rain and sunshine do occur together.'

THIS ANALYSIS OF THE VARIOUS TYPES OF CATEGORICAL AND hypothetical proposition illustrates the fact that the fundamental pattern of the judgment is the same in all: it is the *affirmation or denial of one thing regarding another*; the only difference is this, that in some cases it is *ideas*, and in other cases it is *judgments*, which are compared and about which the agreement or disagreement is asserted. This fundamental pattern, however, assumes a multitude of expressions which manifest themselves in various *types* of propositions. The mind of man is not mechanical and refuses to formulate its judgments in the stereotyped form 'This is (not) that.' In consequence of this tendency of the mind we find propositions ranging all the way from a one-syllable and one-word sentence like 'Fire!' ('Something is burning!') to the complicated structures of sentences containing over a hundred ideas and a dozen part-judgments of previous experiences, united into 'one complete proposition. The propositions used as examples in this chapter are of a comparatively simple nature, because they were chosen to illustrate the construction of each type; but the cursory reading of any book or article will show how the simple judgment can be overlaid and nearly smothered with words. However, a working knowledge of the types of propositions, as explained here, will enable us to unravel the maze of words and detect the truth of the judgment underneath.

SUMMARY OF CHAPTER VIII

The function of language is to convey thought and truth from one mind to another; but the complexity of language tends to cover up the truth of a judgment with words. Hence, there is a necessity to study the various *types* of propositions. Propositions are either single or multiple, categorical or hypothetical. A *single* proposition consists of one subject and one predicate; a *multiple* proposition consists of two or more propositions united into one. A *categorical* proposition attributes (affirms or denies) the predicate to its subject outright; a *hypothetical* proposition asserts the dependence of one judgment on another.

1. *Single categorical* propositions are either complex or modal.

The *complex* categorical is one in which both the subject and the predicate or either one is a *complex term*. The qualifying term is either explicative or restrictive.

The *modal* categorical has the *copula* so modified as to express the manner (mode) in which the predicate belongs to the subject; namely, whether as something necessary or impossible or possible or contingent. This gives rise to necessary, impossible, possible, and contingent propositions.

2. *Multiple categorical* propositions are either overtly or covertly multiple.

The *overtly* multiple propositions are *plainly composed of two or more propositions*. They are five in number: the

copulative, adversative (discretive), relative, causal, and comparative.

The *covertly multiple* have the *appearance of single* propositions; they are called 'exponibles,' and they are five in number: the exclusive, exceptive, reduplicative, specificative, and inceptive-desitive.

3. The *hypothetical proposition* (which is always a multiple proposition) expresses the *dependence of one affirmation or denial* on another affirmation or denial. There are three types of hypotheticals: the conditional, disjunctive, and conjunctive.

Chapter 9

OPPOSITION OF PROPOSITIONS

AFTER EXAMINING THE GENERAL AND SPECIAL TYPES OF propositions, considered alone for themselves, we must now investigate certain *properties* of propositions when *compared to each other*. By this we do not mean the comparison of one proposition with any kind of other proposition, like the comparison of 'All men are mortal' with 'Apples are tasty'; we mean the comparison of one proposition with another, in both of which the *terms* used as *subject* and *predicate* are retained, but with some change in 'quality' or 'quantity' or both, as the comparison between 'All men are mortal' and 'No men are mortal' and 'Some men are not mortal' and 'Some men are mortal.' Truth and falsity are closely linked in these propositions, because they are evidently *opposed* to each other. Given the truth of one, how about the falsity of the others? And given the falsity of the one, how about the truth of the others? An investigation of this *logical opposition* between such propositions will be of importance in determining their truth and falsity and will be of great assistance in detecting and refuting errors in the course of an argumentation.

NATURE OF LOGICAL OPPOSITION

All truth is based upon the *three laws of thought*: the Principle of **Identity**, the Principle of **Contradiction**, and the Principle of the **Excluded Middle**. These principles form the foundation of all human knowledge. They are such that they need no demonstration, because they are self-evident; a mere explanation will suffice to show their truth.

The *Principle of Identity* reads 'Whatever is, is.' It is also stated in these words: 'Everything is what it is.' Or, as others put it: 'A thing is identical with itself.' Its truth is self-evident. The mere statement of the principle is sufficient to show its truth.

The *Principle of Contradiction* [aka 'non-contradiction, ed.] is formulated as follows: 'Whatever is, cannot at the same time not be,' or, 'It is impossible for the same thing both to be and not to be at the same time.' It will be observed at a glance that this principle is but a different expression of the Principle of Identity: if the first is true, then this second is true also. Surely, if a thing 'is,' one cannot say that it 'is not'; otherwise 'is' would be identical with 'is not,' and 'being' would be the same as 'not being,' and a 'thing' would be 'nothing.' This would be absurd on the very face of it. Of course, it is self-understood that we must use the principle of the *same thing at the same time under the same circumstances*. A person may 'sit and stand' at different times, but a person cannot 'sit and stand at the same time'; the latter would be a contradiction and therefore untrue. A person may be 'a boy and a man' at different stages of life, but not at the selfsame moment of

life. While the Principle of Contradiction applies with equal force to the order of reality and to the order of thought, we are here concerned with its application to the *'logical order* of thought only, and it then reads: *'The same attribute cannot at one and the same time be both affirmed and denied of the same thing.'*

The *Principle of Excluded Middle* is expressed in different ways: 'A thing either is or is not'; 'everything must either be or not be'; 'any attribute must be either affirmed or denied of any given subject'; 'two contradictories cannot be false together'; one of the two contradictories must be true'; 'between affirmation and denial there is no middle course'; 'between two contradictories a middle is excluded.' Obviously so. There is no middle thing possible between 'being' and 'not being'; it is either the one or the other. There is no middle stage or state possible between 'is' and 'is not'; it either 'is' or it 'is not.' This is self-evident. When applied to the *logical order*, the Principle of Excluded Middle has the necessary meaning: 'If I make an affirmation, I thereby deny its contradictory; if I make a denial, I thereby affirm its contradictory.'

Here, then, we have the fundamental laws and principles of correct thinking and truth. Keeping them constantly in mind, we will find little difficulty in understanding the properties of propositions when placed in *opposition* to each other. The *logical opposition* of propositions is the *relation which exists between propositions having the same subject and the same predicate, but differing in quality, or in quantity, or in both.*

There are four possible ways in which a proposition, having the same subject and the same predicate, may appear: a universal affirmative (A), a universal negative (E), a particular affirmative (I), a particular negative (O). Here is an example: 'All men are learned,' 'no men are learned,' 'some men are learned,' 'some men are not learned.' These propositions represent the four types of opposition. They are exemplified, together with their mutual relations as 'opposites,' in the sub joined *Square of Opposition*:

Square of Opposition

This diagram illustrates the four types of opposition and the four *relations* resulting from this opposition; namely:

The relation of *subalternation* is the opposition existing between a universal and particular affirmative (A and I), and between a universal and particular negative (E and O).

Both propositions, the universal and particular, are called 'subalterns'; the universal is the 'subalternant' (A and E), while the particular is the 'subalternate' (I and O).

The relation of *contradiction* is the opposition existing between a universal affirmative (A) and a particular negative (O), and between a universal negative (E) and a particular affirmative (I).

The relation of *contrariety* is the opposition existing between a universal affirmative (A) and a universal negative (E).

The relation of *subcontrariety* is the opposition existing between a particular affirmative (I) and a particular negative (O).

LAWS OF LOGICAL OPPOSITION

A little concentration will show us that these various relations of opposition entitle us to formulate certain *laws of truth and falsity* regarding propositions which contain these different relations.

Law of Subalternation: A — I and E — O. This law has two phases, the *first* rule of which states: *the truth of the universal involves the truth of the particular; but the truth of the particular does not involve the truth of the universal.* In other words, if A is true, I must be true; and if E is true, O must be true. A mere explanation will suffice to prove the truth of this rule. What is true of 'all' individuals of a class, must also be true of 'some' of these individuals; because what is true of the 'whole,' must be true of every 'part.' If '*All men are mortal,*' then surely '*Some men are mortal*';

and if 'All monkeys are not polar bears,' then 'Some monkeys are not polar bears' either. On the other hand, if I is true, we cannot conclude that A is true; and if O is true, we cannot argue that E is true. This is also obvious. What is true of 'some' need not be true of 'all'; because what is true of a 'part' of a class, need not be true of the 'whole' class. Bear in mind that it *may* be so, but it *need not* be so; because it might happen that what is said of 'some' pertains to the 'whole' class also, but we cannot argue validly in *virtue of the proposition* from 'some' to 'all' and from the 'part' to the 'whole.' Thus, because 'Some men are learned' we cannot conclude that 'All men are learned'; and because 'Some men are not learned' we cannot argue that 'No men are learned.' We are, therefore, never warranted to judge from the truth of the particular to the truth of the universal, even though *at times* we might strike the truth thereby, as in the cases: 'Some men are mortal,' hence 'All men are mortal'; 'Some men are not irrational,' hence 'All men are not irrational.' From the particular proposition, therefore, we can make no valid conclusion to the universal; the universal will always be doubtful.

The *second* rule of the law of subalternation states: *the falsity of the particular involves the falsity of the universal; but the falsity of the universal does not involve the falsity of the particular.* If I is false, A is false; if O is false, E is false: this is the first part of the rule, and it is plain enough. In order that something be true of 'all,' it must be true of each and *every* individual who makes up the 'all'; that something be true of the 'whole,' it must be true of *every* 'part' contained in the 'whole.' How, then, could something be

true of 'all,' if it is false of 'some'? Hence, if it is false that '*Some* men are learned,' it is all the more false to state that '*All* men are learned'; and if it is false to say that '*Some* men are not mortal,' it is also false to say that 'All men are not mortal.' From the falsity of the particular, therefore, we must conclude to the falsity of the universal. The *second* part of this rule reads: If A is false, I need not be false; and if E is false, O need not be false. In order that a universal be true, *every* individual of the class and *every* 'part' of the 'whole' must be true; hence, the universal will be *false*, if *not every* individual of the universal and *not every* 'part' of the 'whole' is true. This means that if a universal is false, *some* of its individuals must also be false, but *some* (of the others) *may be true*. Of course, here, too, all of the individuals *may* be false, but the falsity of the universal only *entitles* us to conclude that *some* of the individuals are false, leaving the matter undecided whether the *others* are true or false. For instance, if it is *false* that '*All* men are learned,' I cannot say that it is *false* that '*Some* men are learned'; because all I can conclude from the falsity of '*All* men are learned' is this, that '*Some* men *are not* learned.' Similarly, if it is false that '*No* men are learned,' I have no right to conclude that it is *false* to say that '*Some* men *are not* learned'; the only legitimate conclusion that I may draw is that '*Some* men *are* learned.' Hence, the falsity of the universal does not involve the falsity of the particular: the particular may or may not be false together with its universal; the falsity of the subalternant will always be in doubt, when the subalternant is false.

Law of Contradiction: A — O and E — I. This law also has a double phase, of which the *first* rule is: *contradictories cannot be true together*. If A is true, O is false; if O is true, A is false; if E is true, I is false; if I is true, E is false. In an affirmative universal (A) proposition, it is asserted that the predicate is affirmed of each and every individual belonging to the subject: 'All men are mortal.' If this is true, then it must be false to deny this statement of '*some*'; hence, the statement that '*Some* men are *not* mortal' (O) cannot be true. In a negative universal (E) it is asserted that the predicate must be denied of each and every individual belonging to the subject: 'No saints are sinners.' If this statement is true, then it must be false to say that '*Some* saints *are* sinners' (I). What is true of *all* must be true of every one of the class; to state at the same time that 'all are' and 'some are not,' and that 'none are' and 'some are,' would violate the Principle of Contradiction. Hence, if the universal affirmative (A) is true, the particular negative (O) is false; and if the universal negative (E) is true, the particular affirmative (I) is false. The law works also the opposite way: if O is true, A is false; and if I is true, E is false. If it is true that '*Some* men *are not* learned,' it is certainly false to assert that '*All* men *are* learned'; and if it is true that '*Some* dogs are mastiffs,' it must be false to assert that '*No* dogs are mastiff s.' From the truth of the particular negative (O), therefore, follows the falsity of the universal affirmative (A); and from the truth of the particular affirmative (I) follows the falsity of the universal negative (E). The *second* rule of the law of contradiction reads: *contradictories cannot be false together*. If A is false,

O is true; if E is false, I is true; if O is false, A is true; if I is false, E is true. The demonstration of this rule is merely a variation of the foregoing rule and should cause no difficulty. If it is false that '*All* men are learned,' it must be true that '*Some* men are not learned' ($A - O$). If it is false that '*No* men are learned,' it must be true that '*Some* men are learned' ($E - I$). If it is false that '*Some* men are not mortal,' it must be true that '*All* men are mortal.' If it is false that '*Some* men are monkeys,' it must be true that '*No* men are monkeys.' In all these examples, when '*some*' is placed in opposition to '*all*,' we must remember that '*some*' is equivalent to '*at least one, and possibly more.*' We now see the correctness of the following conclusions: from the falsity of the affirmative universal (A) follows the truth of the particular negative (O); from the falsity of the universal negative (E) follows the truth of the particular affirmative (I); from the falsity of the particular negative (O) follows the truth of the universal affirmative (A); and from the falsity of the particular affirmative (I) follows the truth of the universal negative (E).

From the above it will be clear that the contradictory pairs form a *perfect opposition* among themselves: they can be neither true nor false together; one must be true and the other must be false. From this it follows that, to overthrow the truth of any proposition, we must prove the contradictory of that statement: this is required and it is sufficient. If anyone makes the general assertion that '*No* acts of man are immaterial,' all that would be necessary to break down the truth of this statement would be to prove a *single* instance showing that '*At least one* act of man is

immaterial,' because that would entitle a person to make the contradictory statement that 'Some (meaning: at least one, possibly more) acts of man are immaterial.' The reason for this, as we saw when explaining the Principle of Contradiction, is that there is no neutral middle ground between contradictories: a thing either is or is not; if the one is true, the other must necessarily be false.

Law of Contrariety: A — E. The rules are: *contraries cannot be true together; contraries may be false together.* If A is true, E is false; if E is true, A is false. If A is false, E may be true or false; if E is false, A may be true or false.

The correctness of the *first* rule is easily demonstrated with the help of the 'square of opposition.' Suppose the universal affirmative (A) is *true*: 'All men are mortal.' What is the result? According to the Law of Contradiction just explained, O must be *false*; it is therefore false to say that 'Some men are not mortal.' Now, according to the Law of Subalternation: 'the falsity of the particular involves the falsity of the universal'; consequently, E (universal negative) is *false*, and the statement that 'No men are mortal' (E) cannot be true. Hence, if A is true, E is false. The same line of reasoning applies, if we suppose E, the universal negative, to be true: 'No stones have life.' If E is true, its contradictory (I) must be false, namely 'Some stones have life.' And since this particular affirmative (I) is *false*, it also involves (according to the Law of Subalternation) the falsity of its universal (A). 'All stones have life' is therefore also false. Therefore, if E is true, A must be false. This shows that contraries cannot be true together.

The *second* rule is proved in similar fashion by means of the square of opposition.' It is granted that A, the universal affirmative, is *false*: 'All fishes have lungs.' Since this is false, its contradictory (O) must be true: 'Some fishes have not lungs.' But we have seen from the Law of Subalternation, that 'the truth of the particular does *not* involve the truth of the universal.' Hence, although it is true that 'Some fishes have not lungs' (O), we *cannot* conclude from this that its universal (E) is also true and say that 'No fishes have lungs.' E *may* be false. Hence, both contraries may be false. Similarly, let it be granted that E, the universal negative is *false*: 'No professors are learned.' This makes the contradictory (I) *true*: 'Some professors are learned.' Again, 'the truth of the particular does not involve the truth of the universal.' Therefore, the truth of A is not established; it *may* be true to say 'All professors are learned,' but it *may* also be false. Hence, both contraries may be false.

We can therefore conclude the following: From the truth of one contrary we can conclude to the falsity of the other; but from the falsity of one contrary we cannot conclude to the truth of the other. The reason is simple. The contraries are the two *extremes* in a certain sphere, with a middle ground in between; like 'white' and 'black' in the sphere of color, with red and green and blue and other colors between them. Certainly, if a thing is 'white,' it cannot be 'black' or any of the other colors; and if it is 'black,' it cannot be 'white' or any other color. But if it is *not* 'white,' it *need* not be 'black,' because it might be red or blue or any other color; and if it is *not* 'black,' it *need* not be 'white,' for

the same reason. The same relation exists between contrary propositions.

Law of Subcontrariety: $I - O$. The double rule here states: *both subcontraries cannot be false; but both subcontraries may be true*. The *first* rule demands: If I is false, O is true; if O is false, I is true. We will take it as granted that the particular affirmative (I) is *false*: 'Some men are crippled.' Then its contradictory (E) must be *true*: 'Not men are crippled.' But the supposition is that the particular, negative (O) is *also false*: 'Some men are not crippled.' Consequently its contradictory (A) must be *true*: 'All men are crippled.' Therefore, if both I and O could be false together, the result would be that A and E would be *true together*; but we proved by the Law of Contraries a moment ago that contraries cannot be true together. Hence, subcontraries cannot be false at the same time; at least one of the two must be true.

The *second* rule of the subcontraries states that both may be true together: if I is true, O maybe true; if O is true, I may be true. We will suppose that I is *true*: 'Some men are crippled.' The contradictory of this (E) must be *false*, and we cannot say that 'No men are crippled.' But we know from the Law of Subalternation that 'the falsity of the universal does not involve the falsity of the particular.' Hence, even though E is false, we cannot conclude to the falsity of O: the proposition O *may* be true that 'Some men are not crippled.' We can also reverse the argument. If O is *true*, 'Some men are not crippled,' then its contradictory A is *false* that 'All men are crippled.' Since, however, we cannot conclude from the falsity of a universal to the falsity

of the particular (Law of Subalternation), we cannot infer that I is also false: the statement that 'Some men are crippled' *may* be true. Both subcontraries, therefore, may be true together.

Summarizing the results of the four types of opposition (subalternation, contradiction, contrariety, and subcontrariety), we arrive at the following list of *legitimate conclusions*:

If A is true: then I is true. E is false, O is false.

If A is false: then O is true, E is doubtful, I is doubtful.

If E is true: then O is true, A is false, I is false.

If E is false: then I is true, A is doubtful, O is doubtful.

If I is true: then E is false, A is doubtful, O is doubtful. If I is false: then O is true, A is false, E is true.

If O is true: then A is false, E is doubtful, I is doubtful.

If O is false: then I is true, E is false, A is true.

From these relations of 'opposites' it will be clear that we are often entitled to conclude from the truth or falsity of one proposition to the truth or falsity of another. This method of concluding from the truth or falsity of one statement to the truth or falsity of another is called *immediate inference*; it is called 'immediate,' because we can pass directly from the one to the other, without the necessity of adducing any other idea or judgment as proof. The 'square of opposition' and the Three Laws of Thought are sufficient to make their truth or falsity evident, provided

we know *beforehand* that one of these opposites is true or false.

The 'square of opposition,' therefore, with its relations of sub-alternation, contradiction, contrariety, and subcontrariety, will act as a powerful aid toward correct thinking.

SUMMARY OF CHAPTER IX

Propositions are said to be *logically opposed* to each other, when they have the same subject and predicate, but with a change in 'quality' or 'quantity' or both.

1. All truth is based upon the *three laws of thought*: the Principle of Identity, the Principle of Contradiction, and the Principle of the Excluded Middle. The *Principle of Identity* states: 'everything is what it is.' The *Principle of Contradiction* states: 'it is impossible for the same thing both to be and not to be at the same time.' The *Principle of Excluded Middle* states: 'everything must either be or not be (something).' These principles are self-evident and they underlie all being and thinking.

The '*square of opposition*' exemplifies the four types of logical opposition possible between propositions: subalternation, contradiction, contrariety, and subcontrariety.

2. *Subalternation* is the opposition existing between A and I, and between E and O. The *two rules* for subalternation are: the truth of the universal involves the truth of the particular, but the truth of the particular does not involve the truth of the universal; the falsity of the particular involves the falsity of the universal, but the falsity of the universal does not involve the falsity of the particular.

Contradiction is the opposition existing between A and O and between E and I. The *two rules* are: contradictories cannot be true together; contradictories cannot be false together.

Contrariety is the opposition existing between A and E. The *two rules* are: contraries cannot be true together; contraries may be false together.

Subcontrariety is the opposition existing between I and O. The *two rules* are: both subcontraries cannot be false; both sub-contraries may be true.

This method of concluding from the truth or falsity of one statement to the truth or falsity of another is called *immediate inference*.

Chapter 10

EDUCTIONS

THE 'SQUARE OF OPPOSITION,' AS WE HAVE JUST SEEN, PERMITS US to draw certain conclusions from a given proposition to the truth or falsity of its opposites. Every judgment not only *states* something for itself, but it also *implies* something else. A sentence like 'All trees are perennial plants' states definitely that trees are plants which live from year to year; but it also implies thereby that it would be 'false to assert that some trees are not perennial plants.' This is implicitly contained in the first judgment, and it is deduced from it by a process of immediate inference. Logical opposition is only one source of such inferences. There are others. They are called 'eductions.'

An eduction is a process of immediate inference whereby, from any proposition taken as true, we derive others implied in it, though differing from the first in subject or predicate or both. In logical opposition the subject and predicate must retain their place in all opposed propositions. In an eduction, however, subject and predicate may be interchanged at times, without destroying truth; and in a similar manner, the 'quantity' and 'quality' of the original proposition may be altered, without destroying

the meaning. There are two main forms of eduction: obversion and conversion.

OBVERSION

Obversion (or *Equipollence*) is a process of immediate inference, *in which the inferred judgment, while retaining the original subject, has for its predicate the contradictory of the original predicate.* The purpose of obversion is to take an original proposition and, by the addition or subtraction of one or two negations, to make a second proposition which is equivalent (equipollent) in meaning to that of the first. Given the first statement, the second cannot be denied, because, though different in form, they actually mean the same thing. The original proposition is called the '*obvertend*,' the inferred proposition is called the '*obverse*.' Since the obverse proposition has a predicate which is the contradictory of the original predicate, the 'quality' of the copula in the obverse proposition will also have to be changed; hence, if the obvertend proposition is affirmative, the obverse will have to be negative, and if the obvertend is negative, the obverse will have to become affirmative. It will, therefore, be necessary to construct the obverse proposition according to the following rule: *retain the subject, contradict the predicate, negate the copula.* The rule can also be formulated in different words: 'negative the predicate, change the quality of the proposition, but leave the quantity of the proposition unchanged.' Since the 'quantity' remains the same and the 'quality' is changed, obversion gives us the following

results: A obverts to E; E to A; I to O; O to I. Examples will make this clearer.

The A proposition: SaP. It states that 'all S is P'; 'All men are bipeds.' Now, if 'all S is P,' the Law of Contradiction forbids us to say that 'all S is non-P,' and we must therefore *deny* that 'all S is non-P,' and that is done by negating the copula by saying that 'no S is non-P.' We have now carried out the rule of obversion by retaining the subject, contradicting the predicate, and negating the copula. The result is that the obverse proposition must be equivalent to the obvertend. Here, then, is how the original proposition is obverted:

Obvertend A: 'All men are bipeds.'

Obverse E: 'No men are non-bipeds.'

These propositions are truly equivalent. If the whole comprehension of 'biped' is affirmed of 'all men,' then the comprehension of 'non-biped' must be denied of 'all men.' Or to put it in a different way, if the whole class of 'all men' belongs to the class of 'bipeds,' then the whole class of 'all men' must be excluded from the class of 'non-bipeds'; and thus 'No men are non-bipeds' and 'All men are bipeds.'

The E propositions: SeP. In this type of proposition 'no S is P'; 'No insects are vertebrates.' According to the Law of Excluded Middle 'S is either P or non-P.' Now, the original statement as given states that 'no S is P'; hence, 'all S is non-P.' This will give us the two equipollent propositions:

Obvertend E: 'No insects are vertebrates.'

Obverse A: 'All insects are invertebrates.'

And this is true. If the comprehension of 'vertebrates' is excluded from the whole class of 'insects,' then the comprehension of 'non-vertebrates (invertebrates)' must be affirmed of 'all insects.' Or (which is the same thing), if 'no insects' belong to the class of 'vertebrates,' then 'all insects' must belong to the class of 'invertebrates.' Therefore, both the obvertend and the obverse are equipollent in meaning.

The I proposition: SiP. Here we state that 'some S is P'; 'Some automobiles are expensive.' If this is accepted, then the Law of Contradiction demands that we deny that these same some are inexpensive.' This we do by using 'inexpensive' as the predicate and negating the copula, 'some S is not non-P':

Obvertend I: 'Some automobiles are expensive.

Obverse O: 'Some automobiles are not inexpensive.'

Since, in the original statement, the comprehension of 'expensive' is affirmed as belonging to 'some automobiles,' the comprehension of 'non-expensive (inexpensive)' must be denied of these 'some.' Looked at from the standpoint of the subject 'some automobiles,' since they belong to the class of 'expensive' cars, they must be excluded from the 'inexpensive' class. This is why the obvertend and the obverse propositions mean the same thing.

The O proposition: SoP. The O type is a particular negative, 'some S is not P'; 'Some homicides are not murders.' The Law of Excluded Middle demands that 'some

S either is P or is not P.' It is granted in the original proposition that 'some S is not P.' We must, therefore, deny that 'some S is not non-P,' and this is done by negating the copula of this last sentence. A logical oddity is the result: we have a sentence with three negatives, 'some S is not not non-P.' Since, however, the two negatives of the copula neutralize each other, they cancel each other; and so we obtain a particular affirmative as the result, 'some S is (not not) non-P.' Hence, the propositions:

Obvertend O: 'Some homicides are not murders.'

Obverse I: 'Some homicides are non-murders.'

As long as the original statement asserts that the comprehension of 'murders' does not apply to 'some homicides,' we must affirm that the comprehension of 'non-murders' does apply to 'some homicides.' Similarly, since 'some homicides' do not belong to the class of 'murders,' these same 'some homicides' must belong to the class of 'non-murders.' 'Some homicides are non-murders' is therefore equivalent to 'Some homicides are not murders.'

In all these obverse propositions the predicate becomes a *negative term*: but the meaning of such a term is *positive in content*. The terms 'non-biped,' 'invertebrate (non-vertebrate),' 'inexpensive (non-expensive),' 'non-murders,' are not the same as 'nothing'; they mean '*something else*' outside the class of bipeds, 'vertebrates, expensive things, murders.' Hence, they are nego-positive terms, negative in form but positive in meaning. A 'biped,' for instance, is a 'two-legged being' while a 'non-biped' is either a 'no-legged

being' or a 'being with one leg or with more than two legs'; both terms represent separate classes of beings. And so with the other nego-positive terms. Obversion is, therefore, not a mere play on words; it is truly an immediate inference from one class of beings to a different class of beings.

CONVERSION

Conversion is a process of immediate inference, in which the inferred judgment takes the subject of the original proposition for its predicate, and the predicate of the original proposition for its subject. The original proposition is called the 'convertend,' and the inferred proposition is called the '*converse*.'

This interchange of subject and predicate would seem, at first blush, to be quite unwarranted and arbitrary. But it is a perfectly legitimate process, and its use is justified by the very nature of the judgment. Every judgment involves two ideas and the mental act asserting their agreement or disagreement among themselves. The ideas contained in the subject and predicate are perceived by the mind to be such, that they are identical or non-identical; accordingly, the judgment is either affirmative or negative. If they are identical, then it must be equally permissible to affirm the subject of the predicate as it is to affirm the predicate of the subject. If they are not identical, then the predicate is outside the class of the subject just as well as the subject is outside the class of the predicate. In both instances an interchange of the two terms should express the same relation. For example, if it is true that 'Trees are living

things,' it must be equally true that 'Some living things are trees'; and if 'No trees are animals,' then, also 'No animals are trees.' In the first example it is stated that the 'class of trees' belongs to the wider 'class of living things,' and consequently 'some class of living things' is identical with the 'class of trees,' and it must, therefore, be proper to turn the original statement around and state that 'Some living things are trees.' In the second example, we 'exclude the whole 'class of trees' from the whole 'class of animals,' and this also excludes the whole 'class of animals' from the whole 'class of trees,' and so we must be able to assert with equal truth that 'No animals are trees.'

Since it is the purpose of conversion to *infer* a second proposition of equal truth and value from a given original proposition, it is obvious that the second must follow *necessarily* from the truth of the first, and it must contain nothing which is not contained in the first. This demands a *double rule*, in order to insure the strict consequence of the converse from the convertend proposition: *the converse and convertend propositions must retain the same quality, i.e., must both be affirmative or both be negative; no term may be distributed in the converse, unless it was distributed in the convertend.*

It takes but a few moments' reflection to understand the necessity of these two rules. If we assert the identity between subject and predicate in the convertend, we must do the same in the converse, because the converse proposition is supposed to express the same truth and relation as the convertend. For the same reason the converse must be negative, if the convertend is negative. As

for the *second* rule, if a term is not distributed in the convertend, it is a particular term and applies only to a part of the class mentioned. But what is true of a 'part' of a class, need not be true of the 'whole' class, and so we are not allowed to conclude from a 'part' to the 'whole.' It follows, therefore, that a term which is undistributed (i.e., which is used as a particular term) in the convertend proposition may not be distributed (i.e., used as a universal term) in the converse proposition; otherwise we would infer *more* in the converse than is asserted in the original terms. Naturally, though, a term that is distributed in the obvertend proposition may be used as a particular term in the converse proposition, because what is true of the 'whole' must also be true of the 'part.' It will, therefore, be evident that 'no term may be distributed in the converse, unless it was distributed in the convertend'; but a term which is distributed (universal) in the convertend may be undistributed (particular) in the converse.

When the quantity (extension) of subject and predicate is the same in both the convertend and the converse, then such a conversion is called a *simple conversion*; but when the quantity of either subject or predicate, which is universal in the convertend, is limited to a particular term in the converse, then the conversion is called a *conversion by limitation*. And here we must recall that the predicate of an affirmative proposition is always particular and the predicate of a negative proposition is always universal; the subject will be universal in extension, if it is preceded by 'all' or 'every,' and the subject will be particular in extension, if it is preceded by 'some.' After these general

observations, we will consider the conversion of the four types of propositions, A, E, I, O.

Conversion of *A propositions*: SaP. The convertend (original) statement will read: 'all S is P'; 'All roses are plants.' Since this is an affirmative sentence, the predicate is particular. Hence, the converse proposition cannot be made into 'all P is S,' 'All plants are roses,' because 'all plants' would be universal, and that would infer more than the original proposition warrants. A universal affirmative proposition can only be converted *by limitation*, i.e., the converse will have to be an affirmative particular proposition, 'some P is S,' 'Some plants are roses.' Hence, by conversion A becomes I.

Convertend A: 'All roses are plants.'

Converse I: 'Some plants are roses.'

It will be well to note this peculiarity of the A proposition, because many people in the course of an argument are guilty of the fallacy of making a simple conversion here, where only a conversion by limitation is permissible. Nothing is more frequent than the erroneous inference: 'Insane people are eccentric, and therefore eccentric people are insane'; 'cowards are mean people, and therefore mean people are cowards'; 'martyrs are heroes of duty, and therefore heroes of duty are martyrs'; 'murder is homicide, and therefore homicide is murder'; 'hypocrisy is deceit, and therefore deceit is hypocrisy.' Such a course of inference will be correct only when the predicate is co-extensive with the subject, as is the case with *definitions*:

'All men are rational animals, and all rational animals are men.' But we cannot do this *in virtue of the proposition as such*, because the predicate in an affirmative proposition ordinarily is taken only according to a *part* of its extension ('some'), and in consequence of this the predicate must become a particular term when it is used as the subject of the converse proposition. All we are allowed to infer in the above-mentioned examples is:

'Some eccentric people are insane'; 'some mean people are cowards'; 'some heroes of duty are martyrs'; 'some homicides are murders'; 'some forms of deceit are hypocrisy.'

Conversion of *E pro positions*: SeP. Here 'no S is P'; 'no rubies are diamonds.' The subject, of course, is a universal term. And so is the predicate, because the predicate of a negative proposition is always distributed (universal). The negation of the copula signifies that the entire class of S is outside the class of P and, reversely, that the entire class of P is also outside the class of S. By a simple conversion, then, 'no S is P' becomes 'no P is S':

Convertend E: 'No rubies are diamonds.'

Converse E: 'No diamonds are rubies.'

Conversion of *I propositions*: SiP. In virtue of this proposition 'some S is P'; 'Some New Yorkers are millionaires.' The subject is undistributed (particular), as can be seen by the 'some'; the predicate is also undistributed (particular), because it is an affirmative proposition which takes the predicate only according to a

part of its extension. No change of extension, then, is necessary in transposing subject and predicate in the converse, because both terms will again be undistributed. Hence, by simple conversion 'some S is P' becomes 'some P is

Convertend I: 'Some New Yorkers are millionaires.'

Converse I: 'Some millionaires are New Yorkers.'

Conversion of *O propositions*: SoP. The sentence states that some S is not P; 'Some Americans are not Wisconsin citizens.' No conversion at all is possible for the O propositions. The converse would have to read: 'Some Wisconsin citizens are not Americans.' This is false on the face of it, because, if they are 'Wisconsin citizens,' they must be 'Americans.' The reason is not difficult to find why this sort of conversion is not a legitimate inference. The subject of the original (convertend) proposition is a particular term, because we speak of '*some* Americans'; it is, therefore, undistributed. But in the converse proposition this subject becomes the predicate of a negative sentence, and such a predicate is always distributed (universal). Now, what is true of 'some' need not be true of 'all'; what is true of a 'part' need not be true of the 'whole'; no conclusion (as we saw in the 'square of opposition') from the truth of the particular to the truth of the universal is valid. But that is precisely what we would do, if we took a particular subject and made it a universal predicate in a negative proposition. Hence, we cannot convert 'SoP' into 'PoS'; because 'Some Americans are not Wisconsin citizens,' it does not follow

that 'Some Wisconsin citizens are not Americans.' Such an inference may be true, but it would not be true in virtue of the proposition as *such*, and consequently we cannot be sure of the truth of the converse in O propositions.

Before attempting obversion and conversion, the original statement should always be put into *strict logical form*, otherwise errors will inevitably follow. Thus, we cannot say that 'Gangsters killed policemen' and then convert the statement into 'Policemen killed gangsters.' The original proposition must be reduced to 'Gangsters are men who killed policemen'; now we can legitimately convert this sentence into 'Some men who killed policemen are gangsters.' Similarly, it is obvious that we cannot convert the statement 'Criminals kidnaped the 'Lindbergh baby'' into the sentence 'The Lindbergh baby kidnaped criminals.' But, after reducing the first proposition into the strict logical form of 'Criminals are men who kidnaped the Lindbergh baby,' we can validly infer that 'Some men who kidnaped the Lindbergh baby are criminals.' One must be sure of the meaning and then change the wording of the sentence accordingly.

CONTRAPOSITION AND INVERSION

There are two other forms of eduction, *contra position and inversion*. These, however, are hardly more than applications of obversion and conversion; they possess only minor value, and will, therefore, receive only passing mention.

Contraposition takes place when the subject of the inferred proposition is the contradictory of the predicate of the original proposition. Let the original statement be: 'All ants are insects.' The obverse of this is: 'No ants are non-insects.' The contrapositive proposition will then read: 'No non-insects are ants.' In other words, if we convert the obverse of the original statements, we arrive at the contrapositive proposition. The original predicate is 'insects'; its contradictory is 'non-insects'; this, then, becomes the subject of the inferred proposition, and thus we have the contrapositive proposition 'No non-insects are ants.'

If *contraposition* seems an unusual and almost violent method of expressing a judgment, *inversion* is doubly so. *Inversion* is a method of eduction in which the mind, by means of obversion and conversion, finally arrives at a judgment in which the subject is the contradictory of the original subject. Here is a sample inversion:

Original A: 'All men are intelligent.'

Obverse E: 'No men are non-intelligent.'

Converse E: 'No non-intelligent beings are men.'

Obverse A: 'All non-intelligent beings are non-men.'

Converse I: 'Some non-men are non-intelligent.'

Inverse: 'Some non-men are non-intelligent.'

One must be something of a mental contortionist to twist and squirm through a set of obversions and conversions like this, in order to arrive at the inverse proposition. The final result is almost as if the mind were upside down and

standing on its head, so as to obtain the proper perspective and angle of vision in viewing the truth of the inverse. Of course, no one ever thinks this way and no one would ever dream of formulating a judgment in such a manner. It may be ingenious, but it is an unnatural procedure. Its value as an aid to correct thinking is small.

Our study of the judgment and the proposition has given us a better understanding of the mind and its workings. It has shown us how the intellect, after forming ideas of things, compares these ideas with each other and, like a judge in his tribunal, passes a verdict of agreement or disagreement on them. This verdict is expressed in the judgment, an affirmative judgment being an expression of agreement and a negative judgment being an expression of disagreement. Fundamentally, therefore, every judgment must consist of a subject and a predicate and a copula.

Due to the flexibility of the mind, the judgment is molded into a variety of propositions. The main divisions of propositions are the single and multiple categorical and the hypothetical; both these classes are subdivided into numerous types. But no matter how varied the type and how complicated the grammatical structure of these propositions may be, they can all be reduced to the fundamental pattern of a subject, a predicate, and a copula.

The basic purpose of all mental operations is the discovery and proof of truth. In order to proceed safely and accurately in this quest of truth, the mind must know the exact meaning and the full implication of judgments and propositions. Only then can the intellect be sure that its inferences are correct. Logical opposition and the different

types of eduction (obversion, conversion, contraposition, and inversion) supply us with this important insight into the meaning and implication of judgments and enable us to draw immediate inferences from propositions. These immediate inferences, though valuable, are very limited in scope, and the truths discovered by this process of immediate inferences are neither very startling nor far-reaching. Something else is needed. It is reasoning.

Reasoning, then, forms the subject matter of our next investigation.

SUMMARY OF CHAPTER X

Besides the immediate inference of logical opposition, we have the immediate inference of eduction. Eduction is a mental process whereby, *from any proposition taken as true, we derive another implied in it, though differing from the first in subject or predicate or both.*

1. *Obversion* (equipollence) is an eduction in which the inferred judgment, while retaining the original subject, has for its predicate the contradictory of the original predicate. The original proposition is the 'obvertend,' and the inferred proposition is the 'obverse.' The rule for obversion is *retain the subject contradict the predicate, negate the copula.* 'All S is P' becomes 'no S is non-P,' 'no S is P' becomes 'all S is non-P,' 'Some S is P' becomes 'some S is not non-P,' 'Some S is not P' becomes 'some S is non-P.'

2. *Conversion* is an eduction in which the inferred judgment takes the subject of the original proposition for its predicate, and the predicate of the original proposition for its subject. The original proposition is the 'convertend,' and the inferred proposition is the 'converse.' The rules for conversion are: *the converse and convertend must retain the same quality; no term, undistributed in the convertend, may be distributed in the converse.* 'All S is P' becomes 'some P is S.' 'No S is P' becomes 'no P is S.' 'Some S is P' becomes 'some P is S.' The particular negative (O) proposition cannot be converted.

3. *Contraposition* is an eduction in which the subject of the inferred proposition is the contradictory of the

predicate of the original proposition. For instance, 'all S is P' becomes 'no non-P is S.'

Inversion is an eduction in which the mind by means of obversion and conversion finally arrives at a judgment in which the subject is the contradictory of the original subject. For example, 'all S is P' becomes 'some non-S is non-P.'

PART III

INFERENCE AND ARGUMENTATION: DEDUCTION

Chapter 11

NATURE OF REASONING

REASONING IS THE SUPREME OPERATION OF MAN AS MAN. AMONG the ever-changing activities of all the multitudinous beings which constitute this universe, from the gyrations of the infinitesimal electrons to the ponderous wheelings of entire star-galaxies flashing through the immensity of space, there is none which can even remotely compare with the splendid achievement of man's reasoning. Man is the apex which graces the pyramid of beings in Nature. The material and the immaterial, the unorganized and the organized, the non-rational and the rational — all are drawn together in man's essence; he is the representative of all bodily creatures, and they reach their culmination point in his power of reasoning. For it is his power of reasoning which lifts man above and beyond all other things, making him a being apart; it is his grand and solitary prerogative, separating him by an unbridgeable abyss from every other creature in this visible world. Man alone can think and reason.

MEDIATE INFERENCE

Man thinks, when he forms ideas — those intellectual representations of things which image the essences underlying the fleeting shadows of phenomena. Man thinks, when he unites ideas into judgments, thereby overstepping the boundary line of sense and striking out into the realm of universal truth. But most of all, man thinks, when he reasons.

Like all other things in Nature, man reaches the full stature of his perfection only in gradual stages. As in his bodily life, so too in his intellectual growth, he is the product of a slow development. Knowledge comes by degrees. It begins in the senses and ends in reason. In the presence of sense objects man's mind automatically becomes active, first forming a *phantasm* and then fashioning an *idea*. Ideas, at the start, are very vague and most general — 'thing,' 'something.' Then, by means of constant observation and study, the mind distinguishes between the various attributes of objects, accidental and essential, until it has a comparatively full knowledge of the thing in its comprehension and extension. This is accomplished through analysis and synthesis and is expressed in the definition and division. Definition and division are the highest expression of ideas as such, and they rest ultimately on concepts which are so simple and evident that they cannot be defined: these are the transcendental ideas of 'being,' 'thing,' 'substance,' 'accident,' and so forth. They are the foundation of knowledge.

The function of the mind is to attain truth. But truth is not found in the ideas; they contain merely the elements of

truth. Truth resides formally in the *judgment*. Having fashioned ideas, the mind holds them up for inspection, compares them, recognizes their agreement or disagreement with each other, and then pronounces their mutual identity or non-identity in a judgment. We have then two ideas, a subject and a predicate, and the mental act of pronouncement in the copula. Since ideas represent things, the judgment expresses an agreement or disagreement between things as they exist in themselves, independent of the mind; and if the mind's judgment corresponds with reality, it is true, and if not, it is false. Here, then, is real progress in knowledge, because now the mind has arrived at truth. As in the case of ideas, so here in judgments, the mind finally reaches certain judgments which are basic and self-evident and are the foundation of all truth; they are the Principles of Identity, of Contradiction, of Excluded Middle. In virtue of these principles, the intellect, after recognizing a given judgment as true, is capable of drawing some conclusions regarding other judgments which are *implied* in the first; this is done by the process of immediate inference, as the result of logical opposition and eduction. As definition and division are the highest expression of ideas as such, so *immediate inference* is the highest expression of judgments as such.

Immediate inference is a primitive form of reasoning. It does not lead the mind very far on the road of knowledge and truth, because it is merely the explicit statement of what is implicitly contained in a given judgment recognized beforehand as true. Certainly, if I know that 'All men are animals,' I can validly infer that 'Some animals are men';

but there is obviously little advancement of knowledge in this. Many truths can be learned by the analysis of ideas, when compared with each other, as we saw in the analytic *a priori* judgments; but here, too, we are restricted to a limited number. More truths are discovered by the direct process of sense perception. I glance out of my window: 'The sun is shining; there is snow on the ground; it is morning; people are walking on the sidewalk; cars are riding the street; a boy is sliding down an embankment; two little girls are quarreling; people are leaving the church; bells are ringing; a chimney is smoking; a truck is stalled'; and so on. But such judgments are of no particular value for the advancement of knowledge and the discovery of important truths. These truths are commonplace. Upon closer consideration, though, even simple judgments like these contain elements which give rise to deep problems of science and philosophy. The sun: 'Is it large, small? how far away? is it an inexhaustible, eternal source of light and energy?' Light: 'Is it corpuscular? undulatory?' Energy: 'Is it a quality? or mere quantity?' People: 'What is life? the soul? is the soul immaterial? immortal?' Religion: 'Is it fact or fiction? is there a God? is there real morality or only convention?' How can we know? These are problems worthy of solution.

We can obtain no answer to these questions by the sole comparison of ideas. That 'The sun is shining' is a palpable truth; I see it, and I know that the attribute expressed by the predicate 'shining' belongs to the being designated by the subject 'sun.' But if I make the judgment 'The sun is a star about 860,000 miles in diameter,' then neither sense

perception nor an analysis of subject and predicate will permit me to assert the truth of this judgment; there is nothing to show that the predicate must or can be affirmed of the subject. 'God exists; God is a person; God is infinite' — by a mere comparison of subject and predicate I am unable to ascertain the truth or the falsity of these judgments. Similarly, the mere judgment alone will not tell me whether I should state that 'The world had a beginning' or 'The world had no beginning.' Nor is it a self-evident truth that 'Man has a soul'; much less is it clear that 'The soul of man is immaterial and immortal.' In these and in a host of other judgments an inspection of the statement will not reveal the fact whether the comprehension of the predicate is included in the comprehension of the subject. It is here that the reasoning power of man comes into play.

Whenever the mind cannot perceive the agreement or disagreement between two ideas by their mere analysis or by direct observation, it is in a state of doubt. And this state of doubt will remain unchanged, until the mind compares these questionable ideas with a known *third* idea and sees their identity or non-identity with this third. If both are identified with and in this third idea, then they are also identical with each other. This is due to the Principle of Identity, because 'things that are identical with a third must be identical with each other.' But if one of these two ideas is identified with this third, and the other is not, then they also disagree among themselves. This follows from the Principle of Contradiction, because 'two things, of which the one is the same as a third and the other is not, cannot be the same among themselves.' In the first case, we will affirm the one

as a predicate of the other, and in the second case we must deny it as a predicate of the other. Having observed the relation of the two questionable ideas with a third which is known and understood, the mind is now able to express a judgment of agreement or disagreement between the two ideas themselves. This is the fundamental process of *reasoning*.

In its most basic form, therefore, reasoning consists of three judgments: two judgments, in which each of the two doubtful ideas is compared separately with the known third; and one judgment, the conclusion, in which the newly discovered relation of identity or non-identity between the formerly doubtful ideas is now expressed as known and certain. In any and every process of reasoning, then, there must be at least three ideas and three judgments. It will now be readily understood why reasoning is called *mediate inference*: the agreement or disagreement between two doubtful ideas is 'inferred' through the 'mediation' of a third idea with which both are compared. Hence, mediate inference or reasoning is defined as *the process by which, from certain truths already known, the mind passes to another truth distinct from these but necessarily following from them*. This definition may seem somewhat vague, but there are different types of reasoning or mediate inference, and the definition must fit them all.

The two main types of reasoning are deduction and induction. *Deduction is the process of reasoning in which we conclude from a general law or principle to a particular instance falling under the general law or principle*. Suppose there is a doubt in our mind whether the mimosa pudica,

due to its peculiar reaction to the touching of its leaves, possesses sentiency or no sentiency. And then suppose that science has definitely established the law that the nature of a plant is devoid of sentiency. We can now proceed with the following mediate inference:

All plants are devoid of sentiency;
But the mimosa pudica is a plant;
Ergo, the mimosa pudica is devoid of sentiency.

This is a case of deduction. From the general law that 'All plants are devoid of sentiency' we conclude that the 'mimosa pudica,' because it is one of the class of 'plants,' must fall under the general law governing 'all plants,' and therefore 'The mimosa pudica is also devoid of sentiency.'

We can also start out with a hypothetical proposition. The disjunction, if it enumerates all the possibilities, has the effect of a general principle; if we then accept one of these alternatives as true, we must conclude that all the others are false. For instance:

This criminal is either sane or insane;
He is sane;
Ergo, he is not insane.

The reverse process takes place in induction. *Induction is the process of reasoning in which we conclude from the individual cases to the existence of general laws or principles.* Here the general law or principle is in doubt, while the individual instances are known; we therefore

conclude from the truth of the particulars to the truth of the universal. Take this example:

Water, anywhere on land or sea, when at sea level,
freezes in every instance at $+32^{\circ}$ F.
But water anywhere on land or sea is all water.
Ergo, all water freezes at sea level at $+32^{\circ}$ F.

Of course, it has never been attempted to freeze water at every spot on the globe which is at sea level; but since, whenever and wherever done, water always froze, it is rightly concluded that this is a property necessarily connected with the essence of water and has, therefore, the value of a universal law applicable to all water.

This, then, is the nature of mediate inference in general: it is the process by which, from certain truths already known, the mind passes to another truth distinct from these but necessarily following from them. It is characteristic of every such inference that there exists a *logical connection* between the judgments and ideas, in virtue of which the conclusion follows *necessarily* from the others. A *mere sequence* of ideas and judgments, even if true, *does not constitute an inference*. Here is a case in point:

Plants are no minerals;
Metals are no plants;
Ergo, metals are minerals.

The above conclusion has no logical connection with the other judgments. Neither 'minerals' nor 'metals' are

identified with the mediating idea 'plants'; hence, the mediating idea 'plants' shows no relation between the other two ideas as to their agreement or disagreement. The conclusion, therefore, does not follow necessarily from the other judgments. Now take this example:

All inorganic substances are minerals;
Metals are inorganic substances;
Ergo, metals are minerals.

Here we see how the mediating idea 'inorganic substances' establishes an identity between 'minerals' and 'metals,' enabling the mind to draw the conclusion that 'metals are minerals.' The ideas and judgments are not arranged in a mere sequence, as in the previous example; there is a definite logical connection between them all.

From the foregoing we can easily understand what constitutes the matter and form of the mediate inference. The *matter* consists in the various ideas and judgments of the inference. The *form* consists in that special arrangement of ideas and judgments, in virtue of which the conclusion follows *with necessary force* from the given ideas and judgments. This logical connection between ideas and judgments constitutes the *consequence or consistency* of the inference, and it is the specific differentia which distinguishes reasoning from every other mental act.

Consistency must not be confused with truth. Naturally, the very nature of the inference demands that the conclusion *must* be true, if the other judgments are true. But if the conclusion be drawn from judgments of which one

or all are false, then the conclusion may be false. We see this in the following inference:

No fishes are mammals;
The whale is a fish;
Ergo, the whale is no mammal.

This conclusion is untrue, because the statement that 'The whale is a fish' is untrue; but the conclusion follows strictly and legitimately from the preceding judgments, and it would also be true) if the statement that 'The whale is a fish' were true. Sometimes, though, the conclusion may be true, if drawn with consistency, even though the other judgments be false. For instance:

All fishes are mammals;
The whale is a fish;
Ergo, the whale is a mammal.

Here the conclusion is consistently drawn from the preceding judgments and it is also true, although both preceding judgments are untrue. It *happens* to be true in this case. The reason is this: there exists a true mediating idea establishing the identity between 'whale' and 'mammal,' but it is not the idea 'fish.' A little thought will discover the proper mediating idea; as follows:

All vertebrates which suckle their young are
mammals;
The whale suckles its young;
Ergo, the whale is a mammal.

Hence, regarding the relation between *consistency and truth* in mediate inference, we deduce the following rules: *The conclusion, if drawn with consistency from true judgments, must always be true; the conclusion, if drawn with consistency from false judgments, may be true or false.* The only time, therefore, that truth and consistency are certain to go hand in hand, leaving no doubt in the mind as to the truth of a legitimate conclusion, is when the conclusion is drawn with consistency from judgments which are true in themselves.

The greatest difficulty in any type of inference will always be found to consist in discovering whether the judgments composing the inference are true or false. Ultimately, every inference will have to rest upon judgments which are so clear and simple that they are self-evident and need no further proof of their truth. Such are the Principle of Identity, the Principle of Contradiction, the Principle of Excluded Middle. Such, too, are the axioms that 'The whole is greater than its part,' 'What is true of the whole must be true of all its parts.' In this class we must also reckon the analytic judgments, where a mere analysis of subject or predicate will reveal the other, as 'All men are rational animals,' 'All plants are non-sentient, living substances,' and so on; and all judgments which are the result of immediate experience, like 'Snow is cold,' 'fire burns,' 'gold is yellow,'

'iron is hard,' 'water is transparent,' 'liquids flow,' 'pain hurts', 'I live,' and a million similar judgments. They prove themselves. They are self-evident. They are the rock-bottom of truth and the proof which underlies every inference, when the inference is resolved into its final elements. But the farther we get away from these ultimate and simple judgments, the more difficulty we find in establishing the truth of a judgment we wish to use in our process of reasoning.

Supposing we desire to prove that the world had to have a beginning and that, consequently, it is not from eternity. We will have to formulate the proof something like this:

Every contingent being had a beginning;
Every being that changes is a contingent being;
The world is a being that changes;
Ergo, the world had a beginning.

This inference has consistency, and the conclusion, therefore, follows necessarily from the given judgments. But are these judgments *true*? It will be obvious that the truth of these judgments is not self-evident like the judgment that 'The whole is greater than its part,' or that 'Ice is a solid,' or that 'Man is a rational animal.' Each of these statements in the inference given above will demand a lengthy, careful, and exhaustive demonstration, before they can be accepted as true. Such a demonstration, however, may involve the marshaling of a host of facts and minor proofs, before it will be clear to our mind that each of them is really true; and the more complicated the

demonstration, the greater is the liability of error, because of the natural weakness of man's mind.

The falsity of an inference, therefore, will flow from one of two sources: from the *falsity of the judgments* used in the inference, which are supposed to give a true statement of facts, but do not; or from a faulty arrangement of true judgments in the inference, thereby giving us a conclusion that does not follow necessarily from them. The former constitutes the *material* falsity and the latter the *formal* falsity of an inference. The former rests upon a misinterpretation or ignorance of facts; the latter is the result of a violation of the laws of *correct thinking*. In order, then, that an inference be true in every respect, the mind must guard itself against errors of fact and against errors of inconsistency. Logic does not concern itself with the truth or error of facts; that belongs to the province of the sciences and the special departments of philosophy. Logic is the science of correct thinking, and it therefore devolves upon logic to analyze the different types of inferences and lay down the rules which govern each type, so as to guard itself against a violation of the laws of correct thinking and thereby guarantee the *consistency* of the argument. If the laws of these different types of inferences are faithfully observed, the conclusion will of necessity be correct and true, provided the judgments from which it is drawn are also correct and true. Ordinarily speaking, therefore, logic presupposes the material truth of all judgments in the inference (unless they are obviously false) and concerns itself only with the various types of inferences and the

special *laws of thought* which insure their *formal truth and consistency*.

There are, as has been stated before, two main types of mediate inference, *deduction* and *induction*. These must now be considered and studied in detail. The deductive inference is called the syllogism, and it will be treated first. Before we do so, however, it will be necessary to give an explanation of the verbal expression of the mediate inference.

ARGUMENTATION

Just as the verbal expression of the idea is the 'term' and that of the judgment is the 'proposition,' so the verbal expression of the mediate inference is called the *argumentation*, and it is defined as a *discourse which logically deduces one proposition from others*. The propositions from which the conclusion is deduced are called the *premises* or antecedents. The subject and predicate of the conclusion are the extremes; and the subject is called the minor extreme, or simply the *minor* (term), while the predicate is called the major extreme, or simply the *major* (term). The third term or idea with which they are compared in the argumentation is called the *middle* (term). The reason why we name them 'extremes' and 'middle' lies in their relative position; the 'middle' term functions as a mediating or connecting idea between the subject and predicate of the conclusion, in order to show whether the latter agree or disagree among themselves,

and so it occupies a 'middle' position between them as 'extremes':

S-----M-----P.

The predicate of the conclusion is called the 'major'; because the predicate of a sentence as a rule represents a 'class' whose extension is larger (major) than that of the subject; the subject of a sentence is as a rule only one of the members which belong to the predicate-class, and its extension is, therefore, smaller (minor) than the extension of the predicate. A simple sentence like 'All men are animals' shows that the extension of the predicate 'animals' is larger than the extension of the subject 'men.' Hence the terms 'major' and 'minor.' The premise which contains the major term (predicate of the conclusion) is called the *major premise*, while the premise which contains the minor term (subject of the conclusion) is called the *minor premise*; and these designations are standard, no matter in what order the premises follow each other in the argumentation. The sub-joined examples will illustrate the various designations:

Major premise: All animals (M) are substances (P);

Minor premise: All eels (S) are animals (M);

Conclusion: Ergo, all eels(S) are substances(P).

Minor premise: All metals (S) are minerals (M);

Major premise: All minerals (M) are inorganic (P);

Conclusion: Ergo, all metals(S) are inorganic(P).

These two argumentations show us how to discover which of the premises is the 'major' and which is the 'minor.' Starting with the subject (S) of the conclusion, we look for the premise which contains this term (S); that will be the minor premise. The other premise, then, which contains the predicate (P) of the conclusion, will be the major premise. The middle term (M) must occur in the major and minor premises as the 'term of comparison,' but will not occur in the conclusion at all.

After this examination into the nature of the mediate inference, we are ready to study the different types of argumentation, beginning with deduction.

SUMMARY OF CHAPTER XI

Reasoning is the supreme operation of man as man.

1. Man's mind forms ideas of things. Different ideas are then compared and united in a judgment expressing their mutual agreement or disagreement. Truth lies in the judgment. In many cases the agreement or disagreement between the ideas of a judgment is self-evident. In most cases, however, an analysis of subject and predicate or direct observation will not reveal their mutual identity or diversity. Here reasoning is necessary.

2. The mind compares two doubtful ideas with a *third* idea which is known. If both doubtful ideas agree with this third idea, they also agree among themselves; if one agrees with the third, and the other does not, then they also disagree among themselves: in the first case we have an affirmative conclusion, and in the second case a negative conclusion. This is reasoning or *mediate inference*, and it is defined *as the process by which, from certain truths already known, the mind passes to another truth distinct from, these but necessarily following from them*. There are two main types of mediate inference: *deduction*, where we conclude from the general law to a particular instance; and *induction*, where we conclude from the particular instances to the general law.

In order that a mediate inference be truly an inference, there must exist a *logical connection* between the various ideas and judgments, in virtue of which the conclusion follows with necessary force from them; this is called the

consistency of the inference. The various ideas and judgments constitute the *matter*, and the logical connection constitutes the *form* of the inference.

Consistency is not the same as truth. A conclusion may be drawn with consistency from false judgments, giving us a false, though consistent, conclusion. In order that a conclusion be true with certainty, the conclusion must be deduced with *consistency* from *true* judgments. Errors in inferences, therefore, may flow from two sources: from false judgments or from lack of consistency. Logic, the science of correct thinking, is concerned with the laws of thought which will guarantee consistency, and it presupposes the truth of the judgments as such.

3. The verbal expression of the inference is called *argumentation*, which is defined as a *discourse which logically deduces one proposition from others*. The subject of the conclusion is called the 'minor extreme,' and the predicate of the conclusion is the 'major extreme.' The mediating idea between them is the 'middle term.' The propositions from which the conclusion is drawn are the premises; the one containing the 'minor' term is the minor premise, and the one containing the 'major' term is the major premise.

Chapter 12

CATEGORICAL SYLLOGISM

CORRECT THINKING IS THE AIM OF LOGIC, AND THINKING CONSISTS primarily in reasoning. Consequently, it is the function of logic to investigate the various types of argumentation and the rules which govern their consistency, because consistency is the very essence of correct thinking. The two chief divisions of argumentation are deduction and induction. Since argumentations are composed of propositions, and propositions are of two main types, categorical and hypothetical, we obtain two main types of deductive argumentation, the categorical and hypothetical syllogism. The *categorical syllogism*, therefore, will be the first form of argumentation which must now be examined.

NATURE OF SYLLOGISM

The *syllogism* is defined as *an argumentation in which, from two judgments that contain a common idea and one at least of which is universal, a third judgment, distinct from either of the former, follows with necessity*. The fundamental arrangement of the syllogism consists, therefore, of two premises and a conclusion. One of the

premises contains a comparison of the major term (P) with the middle term (M), and the other contains a comparison of the minor term (S) with the middle term (M); the conclusion expresses the agreement or disagreement between the minor term (S) and the major term (P). The syllogism is a *categorical syllogism*, when the *premises are categorical propositions*. Here are two typical examples:

All M is P - All birds (M) have wings (P);
All S is M - All ostriches (S) are birds (M);
All S is P - Ergo, all ostriches (S) have wings (P).

No M is P - No birds (M) are quadrupeds (P);
All S is M - All ostriches (S) are birds (M);
No S is P - Ergo, no ostriches (S) are quadrupeds (P).

These simple categorical syllogisms show us the *nature* of the syllogism as just defined, namely, the pronouncement of agreement or disagreement between the minor (S) and the major (P) terms in the conclusion, due to their identity or non-identity with the middle term (M) in the two premises; in the one case we obtain an affirmative conclusion and in the other a negative conclusion.

If we examine the *general axiom* or principle which underlies the syllogism, we find it expressed in what is called the *Dictum de omni et nullo*—the Law of All and None:

Dictum de omni dicitur de singulis.

Dictum de nullo negatur de singulis.

This axiom can be rendered as follows: 'What is affirmed of a logical whole may be affirmed of a logical part of that whole; and what is denied of a logical whole may be denied of a logical part of that whole.' This sounds a little mystifying, but the meaning is really quite simple. The middle term (M) in the major premise is a 'logical whole' or universal term ('all birds'), and the entire comprehension of the major term ('have wings') is affirmed of the middle term; and since the minor term ('all ostriches') is a 'logical part' or member belonging to the class-extension of the middle term ('all birds'), therefore the entire comprehension of the major term ('have wings') must also be affirmed of the minor term ('all ostriches'); and so the conclusion must be correct that 'All ostriches have wings.' We can illustrate the principle by means of circles and symbols:

All birds (M) have wings (P);

All ostriches (S) are birds (M);

Ergo, all ostriches (S) have wings (P).

The circles represent the principle graphically. M ('all birds') is a universal or 'logical whole' which includes S ('all ostriches'). The M ('all birds') is included in P ('beings with wings'). Therefore S ('all ostriches') is also included in P ('beings with wings'), since it is a 'logical part' or member included in the extension of M ('all birds'). Consequently, the comprehension of P, since it is found in all M, must also be found in all S, and the conclusion holds that 'All ostriches (S) have wings (P).' Here we have the application of the *Dictum de Omni*.

The application of the *Dictum de nullo* is equally clear:

No birds (M) are quadrupeds (P);

All ostriches (S) are birds (M);

Ergo, no ostriches (S) are quadrupeds (P).

Here we see that M ('all birds'), as a 'logical whole' or universal, includes S ('all ostriches') in its extension as a 'logical part or member. But M ('all birds') is excluded from the extension of P ('quadrupeds'). Therefore, S ('all ostriches'), since it falls as a 'logical part' or member under the class-extension of M ('all birds'), must also be excluded

from P ('quad rupeds'); and so the conclusion must be correct that 'No ostriches are quadrupeds,' and thus the axiom of the *Dictum de omni et nullo* is established.

In the examples given above the middle term (M) was the subject of the major premise and the predicate of the minor premise. The arrangement, however, may be changed. The middle term (M) may be shifted to any position in either premise, so that there are four possible arrangements for the categorical syllogism. The following diagrams will illustrate the various positions:

MP	PM	MP	PM
<u>SM</u>	<u>SM</u>	<u>MS</u>	<u>MS</u>
SP	SP	SP	SP

The categorical syllogism may appear in any of these forms and more will be said of them later, when we examine them individually and investigate the particular rules which govern their consistency.

EIGHT GENERAL SYLLOGISTIC RULES

From the nature of the categorical syllogism, as just explained, logicians have developed *Eight General Rules* or canons which govern every type of categorical syllogism and must be rigidly observed; otherwise the consistency of the argumentation will be destroyed, and the conclusion will either be false or will not follow with logical force from the premises.

1. Only three terms may appear in the syllogism.
2. Neither the major nor the minor term may be a universal in the conclusion, if it was only a particular term in the premises.
3. The middle term may not occur in the conclusion.
4. The middle term must be used at least once distributively (i.e., as a universal) in the premises.
5. If both premises are affirmative, the conclusion must also be affirmative.
6. Both premises may not be negative; one at least must be affirmative.
7. If one of the premises is negative, the conclusion must be negative. If one of the premises is a particular proposition, the conclusion must be a particular proposition.
8. No conclusion can be drawn from two particular premises; one at least must be a universal proposition.

In order to assist the memory in retaining these rules, the following mnemonic lines have been devised:

The terms are only three, to this attend;
Nor let the consequent a term extend.
Conclusions ne'er the middle term admit;
At least one premise must distribute it.
Two negatives no consequent can show;
From affirmations no negations flow.
A universal premise you'll provide;
And let conclusions take the weaker side.

These Eight General Rules are a direct product of the very idea and nature of the categorical syllogism, and their truth and application must be thoroughly understood. A familiarization with these rules will enable us to judge the validity of any categorical syllogism that may occur. At the same time, they will give us a deeper insight into the reasoning function of the mind in this type of argumentation. To facilitate their understanding and perceive their necessity as rules of correct thinking, each one will be explained and proved separately. Wherever expedient, symbols will also be used. The customary symbols S, M, P will be used to designate the minor, middle, and major term. A 'p' before any of these terms will signify that they are 'particular' terms; and a 'u' before them will indicate that they are 'universal' terms. It may be well to remind ourselves again that if a proposition has a particular subject, the whole statement is particular; and if the subject is a universal term, the whole statement is universal. Similarly, the predicate of an affirmative sentence is always a particular term, while the predicate of a negative sentence is always a universal term. When a term is used as a 'universal,' it is said to be 'distributed'; and when it is used as a 'particular' term, it is 'undistributed.' Keeping these uses of terms strictly in mind, the understanding and proof of the eight syllogistic rules should not be difficult. Here, then, are the various symbols:

M = middle.

S = minor (subject of conclusion).

P = major (predicate of conclusion).

pM = particular (undistributed) middle term.

uM = universal (distributed) middle term.

pS = particular minor term.

uS = universal minor term.

pP = particular major term.

uP = universal major term.

+ = an affirmative proposition (e.g., M+P).

- = a negative proposition (e.g., M—P).

PROOF OF EIGHT GENERAL RULES

First General Rule: Only three terms may appear in the syllogism. This follows from the very idea of the syllogism as an inference. It is the purpose of the argumentation to discover whether two doubtful ideas agree or disagree by comparing them with a *mediating* idea. This mediating idea is the third, or middle term, with which the other two agree or disagree. A third idea or term must, therefore, always be present. But this very function of the middle term excludes any other idea from the premises, otherwise there would be no common bond of comparison between the two questionable ideas. If the minor term agrees with a third, and the major with a fourth, there will be no necessity to state in the conclusion that they agree or disagree among themselves. The following example and diagram show this plainly:

All plants (M^1) are living (P);
 All stones (S) are minerals (M^2);
 All stones (S) are (are not?) living (P).

Four terms will be used, with an invalid syllogism as the result, if we use an equivocal term in different meanings.

Beings who are not free, are not morally responsible;
 Slaves are not free;
 Ergo, slaves are not morally responsible.
 (Equivocation between 'moral' and 'civil' freedom.)

A frequent source of errors in argumentation results from the introduction of four terms by using the middle term twice as a particular. The fallacy of this will be seen when we treat of the Fourth General Rule, which specifically requires that the middle term be distributed at least once.

Second General Rule: Neither the major nor minor term may be a universal in the conclusion, if it was only a particular term in the premises. The reason is obvious: if either of these terms is a particular term in the premises, then it is taken according to only a part of its extension, and only this part of its extension is identified with the middle

term. Hence, it will also be necessary in the conclusion to identify this major term with the minor term only according to *this part*, since that is all that the premises warrant. It is never permissible to conclude from the truth of the particular to the truth of the universal, as we saw when discussing the 'square of opposition'; because what is true of a 'part' of the extension need not be true of the 'whole' of the extension, since what is true of 'some' may not apply to 'all.' To use a term in the conclusion as a universal, when it is only a particular term in the premises, really amounts to using a *different* term, and results in a four-term construction of the syllogism; and that would be a violation of the First General Rule. This rule is violated most frequently by using the major term (P) as the predicate of an *affirmative* sentence in the premises (such a predicate is always *particular*) and then making it the predicate of a *negative conclusion* (such a predicate is always *universal*).

A violation of this rule is called an *illicit process*: if the major (P) is wider in the conclusion than in the premises, it is an 'illicit process of the major'; and if the fault lies with the minor, it is an 'illicit process of the minor.' The following examples, therefore, involve an illicit process:

uM + pP - All men are animals;

uS - uM - No brutes are men;

uS - uP - Ergo, no brutes are animals. (illicit major)

uM - uP - No birds are viviparous;

uM + pS - All birds are bipeds;

uS - uP - Ergo, no bipeds are viviparous. (illicit minor)

In the first example, the major term ('animals') is undistributed (particular) in the premise, because it is the predicate of an affirmative proposition; but in the conclusion it is distributed (universal), because it is the predicate of a negative proposition. In the second example, the minor term ('bipeds') is undistributed in the premise, because it is the predicate of an affirmative sentence; it should, therefore, also be undistributed in the conclusion, and the conclusion should read 'some bipeds are not viviparous.'

Third General Rule: The middle term may not occur in the conclusion. This follows from the nature of the syllogism, which attempts to discover the agreement or disagreement between the major and minor terms. That is done by comparing them with the middle term, and this takes place in the premises; the conclusion has the sole function of expressing the agreement or disagreement between the major and minor after their relation has been discovered in the premises. Hence, there is no place for the middle term in the conclusion; its purpose has been fulfilled in the premises. This rule is violated in the following examples:

M + P - Aristotle was a philosopher;

M + S - Aristotle was poor;

M + SP - Ergo, Aristotle was a poor philosopher.

M - P - No monkeys are jackrabbits;
M + S - All monkeys are four-handed;
M - SP - Ergo, no monkeys are four-handed
jackrabbits.

Fourth General Rule: The middle term must be used at least once distributively (i.e., as a universal) in the premises. If the middle term were taken as a particular term in both premises, it would never be taken according to the 'whole' of its extension, but both times according to a *part of its extension*, so that M would mean only 'some M.' In that case, however, the minor (S) may agree with one part of M, and P may agree with a *different* part of M; and thus the middle term would be equivalently a *double* term, bringing a four-term construction into the syllogism and thereby violating the First General Rule. Of course, it is possible that both S and P refer to the same part of the extension of M, but we could not know this, unless it were expressly mentioned that the 'some M' mentioned in both premises are the 'same some M'; the form of the syllogism alone will never entitle us to do this. In order, therefore, to avoid the fallacy of a four-term construction, the middle term must be used at least once as a universal term, because what is true of the 'whole' will be true of all its 'parts,' since the 'parts' are contained in the 'whole'; there will thus be no danger of the minor (S) pertaining to a different part of M than the major (P). This fallacy of the undistributed middle usually occurs, when the middle term is used as the predicate of two affirmative premises, since such predicates are always particular terms. The two

subjoined examples show how one can never be certain of the consistency of the conclusion, if the premises contain an undistributed middle; in both cases the middle term is a particular term, because it is the predicate of an affirmative sentence:

$uP + pM$ - All men are mortal;
 $\underline{uS + pM}$ - All negroes are mortal;
 $uS + pP$ - Ergo, all negroes are men.

$UP + pM$ - All men are mortal;
 $\underline{uS + pM}$ - All fish are mortal;
 $uS + pP$ - Ergo, all fish are men.

IN THESE EXAMPLES WE PERCEIVE GRAPHICALLY WHY THE RULE demands that the middle be distributed at least once in the

premises. In both syllogisms M is twice particular, because it is the predicate of two affirmative premises. The form of both syllogisms is identical and both, if correct, should give a true conclusion; but the first conclusion is obviously true, and the second conclusion is obviously false. The circles show us the reason why. In the first example S ('negroes') and P ('men') *happen* to strike the *same* 'part' of M, because 'negroes' belong in the class of 'men'; but in the second example S ('fish') and P ('men') belong to *different* 'parts' of the extension of M, and thereby no relation of identity between S and P is established. Hence, we can never be assured of the consistency of a syllogism, unless the middle term be distributed (i.e., used as a universal term) at least once. To have the middle term undistributed, always carries with it the danger and the uncertainty of a four-term construction.

Fifth General Rule: If both premises are affirmative, the conclusion must also be affirmative. This is quite self-understood. The nature of the syllogism demands it. If both premises are affirmative, then it is affirmed that both the major and the minor terms are identified with the middle term; consequently the Principle of Identity will require that also the conclusion state expressly that the major and minor terms are identified with each other. But this is done in an affirmative conclusion: S is P. A negation is not implicitly contained in two affirmative premises; therefore, a negative conclusion would state something explicitly which is not implicitly contained in the premises, and that would be a violation of the Principle of Contradiction. It is

wrong, therefore, to make an argumentation like the following:

M + P - All lemons are sour;

S + M - Some ripe fruit are lemons;

S - P - Ergo, some ripe fruit are not sour.

Sixth General Rule: Both premises may not be negative; one at least must be affirmative. The very purpose of the syllogism as an inference would be defeated, if both premises were negative. In that case neither the major nor the minor is identified with the middle. Hence, the middle term is no common bond between the two, and it tells us nothing whatever about the relation of agreement or disagreement which exists between them; as a result, the conclusion cannot legitimately make any statement about the identity or diversity existing between the major and minor terms. In other words, if both 'premises are negative, the middle term is no 'middle' at all, since it does not perform the function of a middle term, which is to reveal the agreement or disagreement of major and minor. No conclusion, then, can follow from two negative premises; at least one of them must be affirmative, so that either the major or the minor term will be identified with the middle. The fallacy involved in the violation of this rule, can readily be seen in the following example:

M - P - No animal is a stone;

S - M - No diamond is an animal;

S - P - Ergo, no diamond is a stone.

Some logicians are of the opinion that a legitimate conclusion can be drawn from two negative premises. And they give us as an example the following perfectly consistent syllogism:

What is not metallic is not capable of powerful
magnetic influence.

Carbon is not metallic.

Ergo, carbon is not capable of powerful magnetic
influence.

Here we have apparently three negative propositions, two of which are negative premises. It is well to note, however, that one of these premises is only *apparently* negative, namely, the minor premise 'carbon is not metallic.' Why? Let us consider each sentence carefully. In the major premise we have 'what is not metallic' as the subject; 'is not' is the copula; 'capable of powerful magnetic influence' is the predicate. This is, of course, a negative premise. Note that the subject of this major premise is a *complex term*

('what is *not* metallic'), and it is the middle term, since it also occurs in the minor premise. Now consider the minor premise: 'carbon is not metallic.' Is this really a negative sentence, or a hidden affirmative sentence? It is a hidden affirmative sentence. The word 'not' ('carbon is not metallic') does not belong to the copula 'is,' but to the middle term 'metallic' ('*not* metallic'); this can be seen clearly in the major premise, where the middle term reads 'what is not metallic.' Hence, the minor premise ('carbon is not metallic') consists of the following terms: 'carbon' is the subject; 'is' is the copula; 'not metallic' is the predicate. It is, therefore, really an *affirmative* sentence, although at first sight it would be considered a negative sentence. A slight change in the wording, while leaving the meaning the same, will remove all ambiguity and doubt. Instead of the words 'what is not metallic' make the subject of the major premise to read 'a non-metallic substance'; both phrases mean the same thing here. If we make this substitution and formulate the same syllogism, we will find that the minor premise is obviously affirmative:

M - P - A non-metallic substance is not capable of powerful magnetic influence.

S + M - Carbon is 'a non-metallic substance.'

S - P - Ergo, carbon is not capable of powerful magnetic influence.

We see, then, that the example given is not in violation of the Sixth General Rule; on the contrary, our analysis shows that it really conforms to the rule, since one premise is

negative and the other affirmative (though *apparently* negative). Syllogisms of this sort occur quite frequently, especially when the middle term is a complex term containing a negative particle of speech. Here is a similar example:

‘What is not a compound’ (i.e., a simple substance) is
not divisible;
The soul is ‘not a compound’ (i.e., is a simple
substance);
Ergo, the soul is not divisible.

Seventh General Rule: If one of the premises is negative, the conclusion must be negative; if one of the premises is a particular proposition, the conclusion must be a particular proposition. Logicians often combine the two phases of this rule into one by stating that ‘the conclusion must follow the weaker side.’ A ‘particular’ is considered weaker than ‘a universal,’ because the particular is only a part of the extension of the universal. And a ‘negative’ proposition is weaker than an affirmative proposition, because the negative can only be known through the positive; for instance, we can understand the negative idea ‘sickness’ only then, if we understand the positive idea ‘health,’ because ‘sickness’ is the ‘absence of health.’ And now for the reason of the rule in its two phases.

The *first phase* of the Seventh General Rule states: ‘if one of the premises is negative, the conclusion must be negative.’ The proof of this is simple and can be put in a few words. When one of the premises is affirmative and the

other negative, then one of the extremes (major or minor terms, S or P) *agrees* with middle term (M) and the other disagrees with the middle term (M). But this implies that the major and minor terms (S and P) *disagree among themselves*. Hence, the conclusion must also state that the major and minor terms disagree ('S is not P'), and thus the conclusion must be a negative sentence. This is what the first phase of the Seventh General Rule claims to be necessary.

The *second phase* of the Seventh General Rule states: 'if one of the premises is a particular proposition, the conclusion must also be a particular proposition.' It is immaterial whether both premises are affirmative, or whether one is affirmative and the other negative (both cannot be negative, on account of the Sixth General Rule); the rule applies in either case. First, then, let us consider the case where we have two *affirmative premises*, of which one is *universal* and the other *particular*: the rule demands a 'particular' conclusion, simply because one of the premises is 'particular.' We have, then, the following arrangement in the premises:

Given:

Two affirmative premises.

One of these is universal (universal subject).

One of these is particular (particular subject).

Result:

One subject is universal (universal premise).

One subject is particular (particular premise).

Two predicates are particular (both premises are affirmative, and the predicates of affirmative sentences are always particular).

Now, then, of the four terms in the premises (S—M—M—P) three are particular terms, and only *one* term is *universal*. This one universal term must be the middle (M), because the Fourth Rule demands that 'the middle term must be used at least once as a universal in the premises.' Hence, the three remaining terms (S—M—P) are all *particular*; and, as a consequence of this, also the minor term (S) is particular in the premises. But the minor term (S) is the subject of the conclusion and as such it must also be particular (pS), due to the Second General Rule. Hence, since the subject of the conclusion is a particular term (pS), the *conclusion is a particular proposition*; and that is precisely what the second phase of the Seventh General Rule demands.

We will now investigate whether this second phase of the rule also applies, if one of the premises is *affirmative* and the other *negative*, with one of them a universal proposition and the other a particular proposition: the rule demands that also in this case the conclusion must be a particular proposition. Here, then, is the arrangement in the premises:

Given:

One affirmative premise.

One negative premise.

One of these is universal.
One of these is particular.

Result:

One subject is universal (universal premise).
One subject is particular (particular premise).
One predicate is universal (predicate of a negative sentence is universal).
One predicate is particular (predicate of an affirmative sentence is particular).

Two of these four terms (S—M—M—P) are universal and two are particular. According to the Fourth General Rule, the *middle* term (M) must be one of these *universals*. This leaves three terms (S—M—P) in the premises, of which one is universal and two are particular. Since one of the premises is a negative proposition, the conclusion must be negative (according to the first phase of this Seventh General Rule); therefore the *major* term (P) in the conclusion must be a *universal*, because it is the predicate of a negative sentence. But if the *major* term (P) is universal in the conclusion, it must also be *universal* in the premises, otherwise the Second General Rule would be violated. There are only two universal terms in the premises, and these are now used up by the middle (M) and the major (P) terms. Hence, the minor term (S) is one of the two *particular* terms which remain in the premises. But if the minor term (S) is a particular term in the premises, it must also be a *particular* term in the *conclusion*, due to the

Second General Rule. A particular subject, however, makes the whole proposition particular. Ergo, the conclusion must be particular, and that is exactly what this rule claims.

We thus see the necessity and the truth of the Seventh General Rule: 'If one premise is negative, the conclusion must be negative; and if one premise is particular, the conclusion must be particular.' The first phase of this double rule is violated in the following example:

P - M - No good soldiers are good statesmen;
S + M - The Germans are good statesmen;
S + P - Ergo, the Germans are good soldiers.

The second phase of this rule is not applied in these examples:

M + P - All men are intelligent;
pS + M - Some animals are men;
uS + M - Ergo, all animals are intelligent.

M - P - No negroes are white;
pS + M - Some men are negroes;
uS - P - Ergo, no men are white.

Eighth General Rule: No conclusion can be drawn from two particular premises; one at least must be a universal proposition. The proof of this is similar to the proof of the last rule. There are two possibilities: either both premises will be *affirmative* propositions, or one will be an *affirmative* and the other a negative proposition (the Sixth General

Rule will not allow both premises to be negative). The rule states that both arrangements will lead to an invalid conclusion. Let us see if this is so.

If we suppose *both* premises to be *particular affirmative* propositions, then all four terms (S — M — M — P) used in the premises will be *particular*: the *two subjects* will be *particular*, because the propositions are particular; and the *two predicates* will be *particular*, because both premises are affirmative, and the predicates of affirmative propositions are always particular terms. But if all four terms (S — M — M — P) are particular, then the *middle* term (M) is never taken as a universal, and that is a violation of the Fourth General Rule. Hence, any syllogism which consists of two particular affirmative premises will always be invalid. Here is an example:

pM + pP - Some men are taxi drivers;
pS + pM - Some Americans are me;
pS + pP - Ergo, some Americans are taxi drivers.

This seems to be a legitimate syllogism; but if we substitute the word 'Europeans' for 'taxi drivers,' the fallacy will immediately be apparent.

The *second* possible arrangement would be, if one of the *two particular* premises is *negative* and the other *affirmative*. In this arrangement we have the following terms in the premises:

Two particular subjects (subjects of particular propositions). One universal predicate (the predicate of the negative premise).

One particular predicate (the predicate of the affirmative premise).

Of the four terms (S — M — M — P) three are particular, and one is universal. The *middle* term (M), according to the Fourth General Rule, must be a universal at least once. Consequently, the *major* term (P) will be *particular* in the premise. But the conclusion must be negative (Seventh General Rule), and this negative conclusion will make the *major* term (P) *universal*; this, however, is a violation of the Second General Rule. If we wish to avoid this 'illicit process of the major' and let the major term (P) be the one universal term present in the premises, then there is no other universal term left in the premises, and the middle term will be used *twice* as a *particular*; but this violates the Fourth General Rule. No matter how the syllogism is made, it will contain either an 'illicit major' or an 'undistributed middle.' Hence, also this arrangement is invalid, and we thus see that no conclusion can be drawn from two particular premises. The following example will, therefore, be invalid:

pM + pP - Some orators are American citizens;
pS - uM - Some New Yorkers are not orators;
pS - uP - Ergo, some New Yorkers are not American
citizens.

This, of course, is obviously false. But if we substitute 'demagogues' for 'American citizens,' the conclusion would state that 'Some New Yorkers are not demagogues'; and such a conclusion might seem correct, although it is equally

illegitimate, because the conclusion contains an 'illicit major.' If we change the premises, by making the major premise negative, so as to obtain a universal major term, then we will have an 'undistributed middle,' which is just as bad. For instance:

pM - uP - Some orators are not American citizens;
pS + pM - Some New Yorkers are orators;
pS - uP - Ergo some New Yorkers are not American
citizens.

The Eight General Rules are the indispensable conditions for consistency in the categorical syllogism. If they are observed and if the premises are true statements of fact, the conclusion must of *necessity* be true also. If any of these rules are violated, the conclusion may possibly contain a truth; but this will be *incidental* and will not follow *in virtue* of the argumentation. Certainty can only come with consistency.

Looking back over the eight rules, it will be noted that the first four rules refer to the proper use of the terms, while the other four pertain to the 'quality' and the 'quantity' of the *propositions*. They can be summarized in the brief statement:

'There must be no fourth term, and the middle must be distributed at least once; both premises must not be negative, nor both particular; the conclusion must follow the weaker side of the premises, and must not distribute a term, nor be negative, unless one premise does the same.'

If one is interested in Latin hexameters, he will find the rules expressed in the following lines:

*Terminus esto triplex, major, mediusque, minorque.
Latius hos, quam praemissae, conclusio non vult.
Nequaquam medium capiat conclusio fas est.
Aut semel aut iterum medius generaliter esto.
Ambae affirmantes nequeunt generare negantem.
Utraque si praemissa neget, nihil inde sequetur.
Pejorem sequitur semper conclusio partem.
Nil sequitur geminis ex particularibus unquam.*

The main fallacies which must be guarded against, because they easily escape notice, are: the hidden four-term construction, the undistributed middle, the illicit major or minor, and two particular premises. Argumentations in conversation, books, and articles are usually so cloaked with excess words that a fallacy is not readily detected, unless the argument is arranged in strict logical form and then analyzed according to the rules. The rules, therefore, should be thoroughly understood and memorized and applied.

SUMMARY OF CHAPTER XII

The two chief divisions of argumentation are deduction and induction. The two main types of deduction are the categorical and hypothetical *syllogisms*.

1. The *syllogism* is an *argumentation which, from two judgments that contain a common idea and one at least of which is universal, a third judgment, distinct from either of the former, follows with necessity*. It is a *categorical syllogism*, if the propositions composing it are categorical.

A categorical syllogism consists of two premises and a conclusion. One premise contains a comparison of the major term (P) with the middle term (M), and the other contains a comparison of the minor term (S) with the middle (M). The conclusion expresses the agreement or disagreement of the minor (S) and major (P), as revealed in the premises.

The *general axiom* underlying the categorical syllogism is the *Dictum de omni et nullo*: 'What is affirmed of a logical whole may be affirmed of a logical part of that whole; and what is denied of a logical whole may be denied of a logical part of that whole.'

2. The nature of the syllogism gives rise to the *Eight General Rules*:

(1) Only three terms may appear in the syllogism.

(2) Neither the major nor the minor term may be a universal in the conclusion, if it was only a particular term in the premises.

(3) The middle term may not occur in the conclusion.

(4) The middle term must be distributed at least once in the premises.

(5) If both premises are affirmative, the conclusion must also be affirmative.

(6) Both premises may not be negative; one at least must be affirmative.

(7) If one of the premises is negative, the conclusion must be negative; if one of the premises is particular, the conclusion must be particular.

(8) No conclusion can be drawn from two particular premises; at least one must be universal.

The proof of these eight rules would take us too far in a mere summarization. Consult the individual proofs.

Chapter 13

SYLLOGISTIC FIGURES AND MOODS

ALL AVIATORS ARE DARING; ALTHOUGH THE EIGHT GENERAL RULES enumerated in the last chapter are in themselves sufficient to test the consistency of all categorical syllogisms, it will be of great advantage to examine the various forms in which the syllogism may appear and lay down the special rules which govern each form. These forms are few and the rules simple. The investigation of the validity of a syllogism is thereby shortened considerably. At the same time it enables the mind to understand the peculiarities and characteristics of this type of argumentation much better. This brings us to the *syllogistic figures and moods*; they are the two determining factors in the form of a syllogism.

SYLLOGISTIC FIGURES AND MOODS

By syllogistic *figure* we understand the *disposition of the middle term with respect to the major and minor terms in the premises*. The minor term is always the subject and the major term the predicate of the conclusion; here there can be no change. Whatever variations, then, take place in the relative position of the terms among themselves, occur in

the premises. In the major premise the middle term is compared with the major extreme, and in the minor premise it is compared with the minor extreme. There are, therefore, four possible arrangements, which give rise to four different syllogistic *figures*, depending on the position of the middle term relative to the others. Here we have the diagrammed results:

Fig.1	Fig.2	Fig.3	Fig.4
M - P	P - M	M - P	P - M
<u>S - M</u>	<u>S - M</u>	<u>M - S</u>	<u>M - S</u>
S - P	S - P	S - P	S - P

In Figure 1 the middle term is the *subject* of the *major* premise and the *predicate* of the *minor* premise. Whenever a syllogism occurs in which the terms are arranged in this manner it belongs to Figure 1. Here is an example:

M - P All sentimentalists are a nuisance;
S - M All crooners are sentimentalists;
S - P Ergo, all crooners are a nuisance.

In Figure 2 the middle term is the *predicate* of *both* premises. Example:

P - M No artists are great philosophers;
S - M Some statesmen are great philosophers;
S - P Ergo, some statesmen are not artists.

In Figure 3 the middle term is *subject* of *both* premises.
Example:

M - P All aviators are daring;
M - S Some aviators are Americans;
S - P Ergo, some Americans are daring.

In Figure 4 the middle term is the *predicate* of the *major* premise and *subject* of the *minor* premise. Example:

P - M All senators are politicians;
M - S All politicians are great talkers.
S - P Ergo, some great talkers are senators.

Aristotle considered Figure 1 the 'perfect' syllogism. And rightly so. It is the one figure to which the *Dictum de omni et nullo*, which is the basic formula of the syllogism, applies normally and naturally. It is the model of all other forms of argumentation. In it the mind passes spontaneously from one idea to another, predicating the total comprehension of the major term over to the middle term and then drawing the minor term into the extension of the middle term, so that the total comprehension of the major term is applied to the minor term in the conclusion. When I state that 'All mammals have lungs,' I am stating something about the *nature* of the mammals, and this statement has scientific value. Then, when I state that 'All whales are mammals,' I am including the 'whales' as a class in the wider extension of 'mammals.' And thus I am entitled to apply the comprehension of 'beings which have lungs' to 'whales,' so

that the conclusion 'Whales have lungs' is a natural deduction. The three other 'figures' are correct forms of syllogistic reasoning, but a mere glance at their examples will reveal the fact that they are not as natural for the mind as Figure 1.

Aristotle did not consider Figure 4 a real syllogistic figure, because it is not a direct and natural way of reasoning. The direct and natural way of thinking is to make the idea which has a wider extension the predicate of an idea of narrower extension; hence, this should also be the case in the conclusion. But in Figure 4 the reverse is true. If I take the three ideas 'roses,' 'plants,' and 'living beings,' the direct and natural way to reason would be according to Figure 1: 'All plants are living beings; all roses are plants; ergo, all roses are living beings.' Instead of this, Figure 4 reasons: 'All roses are plants; all plants are living beings; ergo, some living beings are roses.' In this conclusion the idea with narrower extension ('roses') becomes the predicate of an idea with wider extension ('living beings'), and this is not the natural way for the mind to think; the conclusion in Figure 4 is the converse of 'all roses are living beings,' and Figure 4 is thereby shown to be merely a modification of Figure 1. However, since Figure 4 represents a correct (though somewhat unusual) form of reasoning and is really the fourth possible way of arranging the terms in the premises, it will receive the same treatment as the others.

Besides syllogistic 'figures,' we also speak of syllogistic moods, and by *moods* (or, modes) we understand the *arrangement of the premises according to quantity*

(*universality or particularity*) and *quality* (*affirmation or negation*). From the standpoint of 'quantity' each of the four figures can have: both premises universal; or both premises particular; or the major premise universal, and the minor premise particular; or the major premise particular, and the minor premise universal. As regards 'quality' the four figures can have: both premises affirmative; or both premises negative; or the major premise affirmative, and the minor premise negative; or the major premise negative, and the minor premise affirmative. Going back to the customary symbols A, E, I, O, we must recall that A = universal affirmative proposition; E = universal negative; I = particular affirmative; and O = particular negative. Absolutely speaking, then, the following combinations of moods are possible in the construction of premises in *each* of the four syllogistic figures:

A A A A - E E E E

A E I O - A E I O

I I I I - O O O O

A E I O - A E I O

Theoretically, all these combinations are possible. *Practically*, however, *half* of them are *invalid*, because they violate one or the other of the Eight General Rules which govern the syllogism. The Sixth General Rule, for instance, forbids two negative propositions as the premises; this eliminates E E, E O, O E, and O O. The Eighth General Rule forbids two particular propositions to be used as the

premises; and this throws out I I, I O, and O I. The combination I E is also invalid, because this means a particular affirmative major premise and a universal negative minor premise. Now, in this major premise (I) the subject is a particular term (it is a particular proposition) and the predicate is a particular term (it is an affirmative sentence), and consequently the major term (P) will be particular. Since, however, the minor premise is negative (E), the conclusion must also be negative (Seventh General Rule); but then the major term (P), being the predicate of a negative conclusion, is a universal in the conclusion, while in the major premise above it was only a particular term. Hence, this combination (I E) violates the Second General Rule by bringing an 'illicit major' into the conclusion. We thus see that, of the sixteen possible combinations, *only eight can be valid*. The eight valid syllogistic moods are:

A A A A - E E I O
A E I O - A I A A

We must now combine these *various moods* with the four syllogistic *figures* and see what rules govern each figure and how these rules affect the validity of the single moods. It stands to reason that the shifting of the middle term in the different figures will not permit all these moods to be applied in each figure. This will become clear as we study the single figures in turn.

RULES OF THE SYLLOGISTIC FIGURES

First Figure. Here the middle term is the subject of the major premise and the predicate of the minor premise, as we see in the symbolic diagram:

Fig. 1

M - P

S - M

S - P

The rule for this First Figure reads: *The minor premise must be affirmative; the major premise must be universal.* A brief examination will show the necessity of this double rule. The *first* part of the rule demands that the *minor* premise be *affirmative*. If the minor premise of this figure would ever be negative, then the conclusion would also be negative (Seventh General Rule), and the major term (P) in the conclusion, being the predicate of a negative sentence, would be universal (S - uP). However, if the minor premise is negative (as supposed), then the major premise would have to be affirmative, because both premises are not allowed to be negative (Sixth General Rule); and thus the major term (P) would be particular in the major premise, since it is the predicate of an affirmative sentence (M + pP). But then the major term (P) would be particular in the premise and universal in the conclusion, and that would be an 'illicit major' in the conclusion, which is in opposition to the Second General Rule. In order, therefore, to avoid an illicit major in the First Figure, *the minor premise must be affirmative.*

The *second* part of the rule for the First Figure demands that the major premise be universal. The reason is clear. If the major premise were particular, then the middle term (M), since it is the subject of this particular sentence, would be a particular term ($pM \pm P$). Since, however, the minor premise in this First Figure must be affirmative (as demanded by the first part of this rule, just proved), the middle term (M), because it is the predicate of this minor premise, will be particular here also ($S + pM$). Hence, if the major premise were particular, the middle term (M) would be particular in both premises ($pM \pm P$, and $S \pm pM$); but this would involve an 'undistributed middle,' which is against the Fourth General Rule. The only way to obtain a 'distributed middle' is to make the *major premise universal*. Consequently, the necessity of the rule for the First Figure is proved: the minor premise must be affirmative; and the major premise must be universal.

If we now turn our attention to the *moods* which are valid for syllogisms of the First Figure, we find that, of the eight combinations which could possibly be legitimate, *four* are valid and four invalid in this figure. Using symbols instead of sentences, for the sake of brevity and clarity, the results are graphically illustrated in the following diagrams.

A	uM + pP
A	uS + pM
<hr/>	
	uS + pP
(valid)	

A	uM + pP
E	uS - uM
<hr/>	
	uS - uP
(illicit major)	

A	uM + pP
I	pS + pM
<hr/>	
	pS + pP
(valid)	

A	uM + pP
O	pS - uM
<hr/>	
	pS - uP
(illicit major)	

E	uM - uP
A	uS + pM
<hr/>	
	uS - uP
(valid)	

E	uM - uP
I	pS + pM
<hr/>	
	pS - uP
(valid)	

I	pM + pP
A	uS + pM
<hr/>	
	uS + pP
(undistributed middle)	

O	pM - uP
A	uS + pM
<hr/>	
	uS - uP
(undistributed middle)	

The diagrams show clearly that the only *valid* moods for the First Figure are A A, A I, E A, and E I. On comparing them with the rule of the First Figure, it will be noticed that each one follows the rule: ‘The minor premise must be affirmative; the major premise must be universal.’ The moods A E and A O are invalid, because they necessarily bring an ‘illicit major’ into the conclusion, and this is due to the fact that they violate the first part of the rule for the First Figure: ‘The minor premise must be affirmative.’ The moods I A and O A are invalid, because an ‘undistributed middle’ is the result of such an arrangement, due to violating the second part of the rule for the First Figure: ‘The major premise must be universal.’

The following examples are verbal illustrations of the four *valid* moods of the First Figure:

A - Every passion causes emotional instability;

A - Greed is a passion;

Ergo, greed causes emotional instability.

A - Excessive hoarders of money are misers;
I - Some lawyers are excessive hoarders of money;
Ergo, some lawyers are misers.

E - No quadrupeds have wings;
A - All donkeys are quadrupeds;
Ergo, no donkeys have wings.

E No thieves will prosper;
I Some politicians are thieves;
Ergo, some politicians will not prosper.

Second Figure. In the construction of this figure, the middle term is the predicate in both premises. The diagram shows the relation of the middle term to the major and minor extreme:

Fig. 2

P - M

S - M

S - P

The rule for the Second Figure is: *One premise must be negative; the major premise must be universal.* The *first* part of this rule states that one premise must be negative. Neither the major nor the minor premise is specified; so it makes no difference which of them will be negative. The reason for this part of the rule is obvious from the very nature of the figure as constructed. In both premises the middle term (M) is the predicate, and if both are

affirmative, then the middle term would be twice particular ($P + pM$, and $S + pM$); as such it would violate the Fourth General Rule, because we would have an undistributed middle. The only way in which the middle term can be used in a distributed sense, so as to avoid violating the Fourth General Rule, is to make one of the two premises negative; then, since the predicate of a negative proposition is always universal, the middle term would be distributed at least once. Hence, *one premise must be negative*.

The second part of this rule states that the *major* premise must be *universal*. A little reflection will disclose the necessity of this. In the major premise the subject is the major term (P). Now, since one of the premises in this figure must be negative, the conclusion will also be negative, in virtue of the Seventh General Rule, and consequently the major term there will be universal ($S - uP$). Since, however, the major term (P) is universal in the conclusion, it must also be universal in the major premise; otherwise we would have an- 'illicit major' and violate the Second General Rule. But if the major term (P) is universal in the premise, then the whole premise as a proposition is universal, because the major term (P) is the subject of that premise. Hence, if we wish to avoid an 'illicit major' in the Second Figure, *the major premise must be universal*. The whole rule of the Second Figure, therefore, is true: one premise must be negative, and the major premise must be universal.

Of the eight legitimate moods which could possibly come into account in this Second Figure, *four* will be discovered to be valid and four invalid. A study of the subjoined diagrams will show this:

A	uP + pM
A	uS + pM
<hr/>	
	uS + pP
<hr/>	
(undistributed middle)	

A	uP + pM
E	uS - uM
<hr/>	
	uS - uP
<hr/>	
(valid)	

A	uP + pM
I	pS + pM
<hr/>	
	pS + pP
<hr/>	
(undistributed middle)	

A	uP + pM
O	pS - uM
<hr/>	
	pS - uP
<hr/>	
(valid)	

E	uP - uM
A	uS + pM
<hr/>	
	uS - uP
<hr/>	
(valid)	

E	uP - uM
I	pS + pM
<hr/>	
	pS - uP
<hr/>	
(valid)	

I	pP + pM
A	uS + pM
<hr/>	
	uS + pP
<hr/>	
(undistributed middle)	

O	pP - uM
A	uS + pM
<hr/>	
	uS - uP
<hr/>	
(illicit major)	

The only *valid* moods for the Second Figure are A E, A O, E A, and E I, and each follows the double rule that 'one premise must be negative, and the major premise must be universal.' Any other combination will violate one of the Eight' General Rules. Because of the peculiar position of the middle term (M) as predicate in both premises, no combination which would involve two affirmative premises can be valid; because this would give us two 'undistributed middle' terms in violation of the Fourth General Rule. That is why A A, A I, and I A are not legitimate moods of the Second Figure. The mood O A is eliminated, because the fact that the major premise here is a particular proposition brings an 'illicit major' into the conclusion in opposition to the Second General Rule. Comparing the moods A A, A I, and I A with the special rule of the Second Figure, we find that they do not follow the first part of this rule which demands that 'one premise must be negative'; while the mood O A does not follow the second part of this special rule, namely, 'the major premise must be universal.'

And now for an example of each of the *valid* moods of the Second Figure.

A - All men are rational;
E - No monkeys are rational;
Ergo, no monkeys are men.

A - All dunces are awkward;
O - Some students are not awkward;
Ergo, some students are not dunces.

E - No poor people are money-lenders;
A - All bankers are money-lenders;
Ergo, no bankers are poor people.

E - No real artists are devoid of imagination;
I - Some poets are devoid of imagination;
Ergo, some poets are not real artists.

Third Figure. Here the position of the middle term (M) is the reverse of that occupied in the Second

Figure; it is the subject of both premises, as will be seen from the diagram:

Fig. 3

M - P

M - S

S - P

The *rule* which governs the Third Figure reads: *The minor premise must be affirmative; the conclusion must be particular.* To this should really be added: *one of the premises must be universal.* If one of the premises were not universal, but both particular, then the middle term, which is the subject of both premises, would be 'undistributed,' and that would violate the Fourth General Rule. However, the matter is already taken care of by the Eighth General Rule, which states that no conclusion can be drawn from two particular premises; and so no special rule is necessary to cover the contingency of an 'undistributed middle' by having two particular premises. Hence, the two-part rule, as given above, will suffice.

The *first* part of the rule requires that the *minor* premise must be *affirmative*. Naturally. If it were ever negative, then the major premise would have to be affirmative, because the premises cannot consist of two negative propositions (Sixth General Rule). But in that case the major term (P), which is the predicate of the major premise in the Third Figure, would be a particular term, because it is the predicate of an affirmative sentence (M + pP). However, due to the Seventh General Rule, a negative minor premise would necessitate a negative conclusion; and that would make its predicate, which is the major term (P) a universal term (S - uP), thereby introducing an 'illicit major,' violating the Second General Rule. This result will occur every time the minor premise is negative; the minor premise, therefore, can never be negative. In order to avoid an 'illicit major,' then, *the minor premise must be affirmative.*

The second part of the rule for the Third Figure requires that the *conclusion be particular*. This should be obvious. The minor term (S) will always be a particular term in the premise, because the minor premise must be affirmative, according to the first part of the present rule, and in this minor premise it (S) is the predicate; and the predicate of an affirmative sentence is always particular (M + PS). But the minor term (S) is the subject of the conclusion; hence, it must also be a particular term in the conclusion, else we would have an 'illicit minor' there and thereby violate the Second General Rule. It will, therefore, be necessary that the *conclusion be particular*.

And so we see that the rule stands: the minor premise must be affirmative, and the conclusion must be particular.

Due to the rule of the Third Figure, that the minor premise must be affirmative, any mood which contains a negative minor premise is automatically eliminated. This happens in two of the eight possible moods, leaving *six valid* moods for this particular figure. As in the preceding figures, the diagram of symbols will reveal the reason why this must be so:

A	uM + pP
A	uM + pS
<hr/>	
	pS + pP
(valid)	

A	uM + pP
E	uM - uS
<hr/>	
	uS - uP
(illicit major)	

A	uM + pP
I	pM + pS
<hr/>	
	pS + pP
(valid)	

A	uM + pP
O	pM - uS
<hr/>	
	pS - uP
(illicit major)	

E		uM - uP
A		uM + pS
<hr/>		
		pS - uP
(valid)		

E		uM - uP
I		pM + pS
<hr/>		
		pS - uP
(valid)		

I		pM + pP
A		uM + pS
<hr/>		
		pS + pP
(valid)		

O		pM - uP
A		uM + pS
<hr/>		
		pS - uP
(valid)		

Here we see plainly that only two moods are invalid in this Third Figure, namely, A E and A O; in each case we have a negative minor premise, introducing an ‘illicit major’ (P) in the conclusion. This bears out the necessity of the rule that ‘the minor premise must be affirmative.’ In all the other moods, A A, A I, E A, E I, I A, and O A, we have an affirmative minor premise, and they are all valid. It will also be noticed, that in each valid mood the minor term (S) is the predicate of an affirmative minor premise, and it thereby becomes a particular term (M + pS). Hence, in order to avoid an ‘illicit minor in the conclusion, the minor term (S) must always be a particular term (PS) also in the conclusion.

The six examples which follow show us how syllogisms can be made according to the six valid moods of the Third Figure:

A - All birds have wings;
A - All birds are bipeds;
Ergo, some bipeds have wings.

A - All fools think themselves wise;
I - Some fools are professors;
Ergo, some professors think themselves wise.

E - No misers are spendthrifts;
A - All misers are people who abuse wealth;
Ergo, some people who abuse wealth are not spendthrifts.

E - No bodies are immaterial;
I - Some bodies are elements;
Ergo, some elements are not immaterial.

I - Some socialists are revolutionary;
A - All socialists are radicals;
Ergo, some radicals are revolutionary.

O - Some criminals do not steal;
A - All criminals are lawbreakers;
Ergo, some lawbreakers do not steal.

Fourth Figure. This syllogistic figure is the reverse of the First Figure, for here the middle term (M) is the predicate of the major premise and the subject of the minor premise.

Fig. 4

P - M

M - S

S - P

A triple rule governs the consistency of the syllogism in this figure, each part of the rule depending on a condition: *If the major premise is affirmative, the minor premise must be universal; if the minor premise is affirmative, the*

conclusion must be particular; if one of the premises is negative, the major premise must be universal. Keeping the general arrangement of the terms of this figure constantly in view, we can readily perceive the necessity of each of these three parts of the rule.

The first part claims that 'if the major premise is affirmative, the minor premise must be universal.' The reason is not hard to find. In the major premise, if it were affirmative, the middle term (M), being the predicate of an affirmative sentence, would be particular. But the middle term (M) is also the subject of the minor premise. Now, if the minor premise were not universal, it would be particular, and that would mean that its subject, which in this case is the middle term (M), would be particular. Both middle terms would then be particular in the premises, and that involves an 'undistributed middle,' violating the Fourth General Rule. Therefore, *if the major premise is affirmative, where the predicate (M) will have to be particular, the minor premise must be universal*, so that the middle term will be distributed at least once.

The *second* part of the special rule for the Fourth Figure says: 'If the minor premise is affirmative, the *conclusion* must be *particular*.' Here, too, the reason is plain. If the minor premise is affirmative, its predicate, which is the minor term (S), will be particular, being the predicate of an affirmative sentence. But this minor term (S) is also the subject of the conclusion, and it must, therefore, also be particular in the conclusion, otherwise we would have an 'illicit minor' in the conclusion, which is against the Second General Rule. Hence, the necessity of this second part of

the rule: *If the minor is affirmative, the conclusion must be particular.*

The *third* part of this rule states: 'If one of the premises is negative, the *major* premise must be *universal*.' Undoubtedly. In this figure the major term (P) is the subject of the major premise. Now, if one of the premises is negative, the conclusion will also be negative (Seventh General Rule), and then this major term would be universal (uP), because it is the predicate of a negative conclusion. Since the major term (P) is the subject of the major premise, it will have to be a universal term (uP), otherwise it would be wider in the conclusion than in the premises, and this would be an 'illicit major' (Second General Rule). Hence, the major term must be a universal term in the major premise, and that means a universal major premise. Consequently the rule is correct, that *if one of the premises is negative, the major premise must be universal*. All three parts of the special rule for the Fourth Figure are thus proved to be necessary, in order to insure consistency in this figure.

If we now investigate the eight possible *moods*, we find that *five* are valid and three are invalid in this Fourth Figure:

A		uP + pM
A		uM + pS
<hr/>		
		pS + pP
<i>(valid)</i>		

A		uP + pM
E		uM - uS
<hr/>		
		uS - uP
<i>(illicit major)</i>		

A		uP + pM
I		pM + pS
<hr/>		
		pS + pP
<i>(undistributed middle)</i>		

A		uP + pM
O		pM - uS
<hr/>		
		pS - uP
<i>(undistributed middle)</i>		

E		uP - uM
A		uM + pS
<hr/>		
		pS - uP
<i>(valid)</i>		

E		uP - uM
I		pM + pS
<hr/>		
		pS - uP
<i>(valid)</i>		

I		pP + pM
A		uM + pS
<hr/>		
		pS + pP
<i>(valid)</i>		

O		pP - uM
A		uM + pS
<hr/>		
		pS - uP
<i>(illicit major)</i>		

Looking over the eight possible moods, we immediately perceive that A I and A O do not conform to that part of the rule of this figure which says: 'If the major premise is affirmative, the minor must be universal.' In consequence of this we have a particular middle (pM) in the major premise, because the middle term is here the predicate of an affirmative sentence (P + pM), and we have also a particular middle term (pM) in the minor premise, because here the middle term is the subject of a particular proposition. Hence, we have an 'undistributed middle' (pM) in both premises of A I and A O, violating the Fourth General Rule. The mood O A will always be invalid in this figure, because it is in opposition to the third part of the rule of the Fourth Figure: 'If one of the premises is negative, the major premise must be universal.' The proposition o is a particular negative sentence, and the major term (P), which is the subject here, becomes a particular term (pP). The conclusion, however, must be negative, because one of the premises is negative (Seventh General Rule), and the predicate of the conclusion must be universal (uP), being the predicate of a negative sentence.

Hence, the major term in the conclusion, being universal (uP), is wider than in the premises, where it is particular (pP - uM), and thus the conclusion contains an 'illicit major'; and that violates the Second General Rule. All the other moods, A A, A E, E A, E I, and I A, observe the special rules of the figure and the Eight General Rules of the syllogism and are, therefore, valid for this Fourth Figure.

As a verbal illustration of the five *valid* moods of this figure, we submit the following examples for perusal:

A - All murders are crimes;
A - All crimes are something detestable;
Ergo, something detestable is murder.

A - All animals are sentient beings;
E - No sentient beings are lifeless beings;
Ergo, no lifeless beings are animals.

E - No plants are sentient beings;
A - All sentient beings are living beings;
Ergo, some living beings are not plants.

E - No inorganic bodies are living beings;
I - Some living beings are sentient beings;
Ergo, some sentient beings are not inorganic bodies.

I - Some bodies are plants;
A - All plants are living beings;
Ergo, some living beings are bodies.

From the above analysis of the four syllogistic figures and the valid moods in each, we see that there are four valid moods in the First Figure, four in the Second Figure, six in the Third Figure, and five in the Fourth Figure. There are, consequently, exactly *nineteen* different ways in which the *simple categorical syllogisms* may validly be formulated. Any other formulation would entail a violation of one of the Eight General Rules which must be observed in this type of argumentation, in order to insure consistency. All these nineteen combinations are valid and correct forms of argumentation, based on the general three-term plan of the syllogism.

The syllogism, as studied so far, is the *standard* form of mediate inference; it is the fundamental pattern of argumentation. It should be clearly understood, and a second reading of this portion will be time well spent.

SUMMARY OF CHAPTER XIII

The categorical syllogism is built up of figures and moods.

1. The syllogistic *figure* is defined as the *disposition of the middle term with respect to the major and minor terms in the premises*. There are four syllogistic figures. In the First Figure the middle term is the subject of the major premise and the predicate of the minor premise. In the Second Figure the middle term is the predicate of both premises. In the Third Figure it is the subject of both premises. In the Fourth Figure it is the predicate of the major premise and the subject of the minor premise.

The syllogistic *mood* is defined as the *arrangement of the premises according to quantity and quality*. There are eight possible valid moods: A A, A E, A I, A O, E A, E I, I A, and O A.

2. *First Figure*. The rule: the minor premise must be affirmative; the major premise must be universal. There are four valid moods in this figure: A A, A I, E A, and E I.

Second Figure. The rule: one premise must be negative; the major premise must be universal. This figure has four valid moods: A E, A O, E A, and E I.

Third Figure. The rule: the minor premise must be affirmative; the conclusion must be particular. Here we have six valid moods: A A, A I, E A, E I, I A, and O A.

Fourth Figure. The rule: if the major premise is affirmative, the minor premise must be universal; if the minor premise is affirmative, the conclusion must be particular; if one of the premises is negative, the major

premise must be universal. There are five valid moods in this figure: A A, A E, E A, E I, and I A.

All in all, there are *four syllogistic figure*: and *nineteen valid moods*.

Chapter 14

VARIETIES OF CATEGORICAL SYLLOGISMS

THE STANDARD CATEGORICAL SYLLOGISM, ONCE ITS FIGURES AND moods are thoroughly understood, offers no undue complications, because its propositions are simple and plain. The mind, however, usually does not run in such plain and simple grooves while performing an act of syllogistic reasoning. Any sort of categorical proposition may be used in the construction of an argumentation, and there will be as many varieties of the categorical syllogism as there are varieties of categorical propositions. Some of them may be complex or modal, and some of them may be multiple propositions. Each kind presents its own special difficulties, which often perplex the mind and give rise to numerous fallacies, unless they are analyzed carefully and the component parts studied separately.

The *general rule* is: Divide the multiple categorical proposition into its component statements and reduce each part to the standard syllogism according to figure and mood; keep a strict control over the terms, and consider the meaning more than the words; then apply the general and special rules pertaining to the syllogism. In order to test the consistency of an argumentation, we are always permitted

to change the wording, if necessary, as long as the meaning of the proposition is not destroyed or impaired, because people are usually somewhat loose in the employment of terms to express their ideas. After all, ideas count, not words. Bearing this in mind, we will now consider the different varieties of syllogisms which result from the presence of the manifold types of categorical propositions in the premises.

COMPLEX AND MODAL SYLLOGISMS

The single *complex* proposition should offer no special difficulty, provided the complex terms are held strictly together and are used in the same combination throughout the argumentation. If a term is modified in any way by another term or clause, whether explicative or restrictive, it should remain so in the entire process of reasoning; otherwise we will run the risk of a four-term construction, with a correspondent violation of the First General Rule. The following syllogism is wrong, because the middle term 'racing automobile,' which is complex, is not retained in its completeness:

All racing automobiles are high-gearred cars;
All Fords are automobiles;
Ergo, all Fords are high-gearred cars.

Sometimes it seems that a complex term is split, one part being united to one term and the other part being linked with another term, thereby introducing more than three

terms. Upon analysis, however, the meaning of such argumentations is found to be correct by a change of wording. Take the following:

George Washington was the first United States president;
Mary Ball Washington was the mother of George Washington;
Ergo, Mary Ball Washington was the mother of the first United States president.

Here 'George Washington' is obviously the middle term. But in the minor premise it is 'the mother of George Washington.' The major term in the major premise is 'the first United States president,' while in the conclusion it is 'the mother of the first United States president.' However, if we look at the *meaning*, the argument can be resolved as follows:

The mother of George Washington was the mother of the first United States president;
Mary Ball Washington was the mother of George Washington;
Ergo, Mary Ball Washington was the mother of the first United States president.

Some propositions, from a grammatical standpoint, contain a principal and an incident clause; logically, however, when considering the meaning, we find that the

incident clause is often the principal clause. Here is a case in point:

It is true that all good democrats are patriotic;
It is equally true that F. D. Roosevelt is a good
democrat;
Ergo, it is true that F. D. Roosevelt is patriotic.

Here we seem to bring a part of the middle term into the conclusion. But the meaning is obvious. Logically speaking, the phrase 'it is true that' is superfluous; it adds no new idea and can be omitted entirely, so that the real syllogism will read:

All good democrats are patriotic;
F. D. Roosevelt is a good democrat;
Ergo, F. D. Roosevelt is patriotic.

Special precaution must be taken, when the qualifying clause or complex term contains a negation. The peculiarity of such a complex term has been discussed before, in giving the proof for the Sixth General Rule of the syllogism; loose language here is responsible for an apparent violation of the laws of correct thinking, while in reality the reasoning may be perfectly valid. A slight alteration of the wording will usually make the test of validity easy; this can be seen in the following legitimate syllogism, where the minor premise is really affirmative:

All athletes who do not train will not be champions;
Some pugilists do not train (i.e., are athletes who do
not train);
Ergo, some pugilists will not be champions.

Modal propositions as premises are best resolved by changing the sentence in such a manner that the 'mode' is made a part of a term, instead of being a statement. Here, too, one must look more to the meaning than to the mere sequence of words. Take this:

It is necessary at times that a nation go to war;
America is a nation;
Ergo, it is necessary at times that America go to war.

The meaning is clear:

All nations at times must go to war;
America is a nation;
Ergo, America at times must go to war.

It is best to refrain from formulating argumentations in which each premise contains a different kind of 'mode'; for instance, when one premise includes a 'mode of necessity' and the other a 'mode of possibility.' This is called 'the cross of the logicians,' because of the difficulty in determining which of these 'modes' should be allowed in the conclusion. The following example will illustrate the difficulty:

It is necessary that all soldiers be brave;
It is possible that some soldiers be heroes;
It is possible (necessary?) that some heroes be brave.

Here, too, a change in wording will help considerably in arriving at a correct conclusion. If we put the 'mode of necessity' into the verb of the major premise and make the 'mode of possibility' an adjective in the minor premise, the solution will be easy:

All soldiers must be brave;
Some soldiers are possible heroes;
Ergo, some possible heroes must be brave.

OVERTLY MULTIPLE SYLLOGISMS

From the complex and modal syllogisms we now pass on to those containing *overtly and covertly multiple propositions* in the premises. In these types the rule must be strictly observed:

In case of doubt *resolve the multiple proposition into its component propositions and arrange each one into a separate syllogism, testing each syllogism according to the rule of the figure into which it falls.* The overtly multiple propositions are, as we know, *five* in number: copulative, adversative, relative, causal, and comparative.

The syllogism containing one or two *copulative* premises should present no special difficulty. In most instances the sense of the propositions is so clear that no reduction should be necessary; as when we reason:

All mammals are vertebrates, are viviparous, and
have lungs;
All kangaroos are mammals;
Ergo, all kangaroos are vertebrates, are viviparous,
and have lungs.

But if we wish, we can construct three syllogisms from
this one, using each of the major terms 'vertebrates,'
'viviparous,' and 'having lungs' separately. Like this:

All mammals are vertebrates;
All kangaroos are mammals;
Ergo, all kangaroos are vertebrates.

All mammals are viviparous;
All kangaroos are mammals;
Ergo, all kangaroos are viviparous.

All mammals have lungs;
All kangaroos are mammals;
Ergo, all kangaroos have lungs.

The *adversative* proposition is similar to the copulative.
The component parts can be reduced to separate
syllogisms; as a rule, however, this will be found
unnecessary. In the following example the adversative
portion of the sentence, 'though difficult,' forms an integral
part of the major term and should remain with it
throughout:

All parts of philosophy are important, though difficult;
Now, logic is a part of philosophy;
Ergo, logic is important, though difficult.

Since both terms, 'important' and 'difficult,' are parts of the major term, it stands to reason that the conclusion may take one or both of these parts, if so desired; it would thus be equally legitimate to simply conclude: 'Logic is important' or 'Logic is difficult' or 'Logic is both important and difficult' or 'Logic is important, though difficult.'

The *relative* proposition introduces the element of time or place in relation to which something occurs. This should cause no particular trouble, as long as this relation is not transferred to some part or term to which it does not belong.

After winning the war the Allies divided the spoils
among themselves;
Now, all nations, dividing the spoils of war among
themselves, make permanent enemies;
Ergo, the Allies, after winning the war, made
permanent enemies.

Except for the wording and for the fact that the minor premise is placed first, this syllogism is correct and the conclusion legitimate.

Every *causal* proposition used as a premise is in itself an abbreviated syllogism, in which the part giving the reason or cause and expressed by the particle 'because' or 'for' contains the middle term. After constructing the complete

sylllogism by using the two parts of the causal proposition as the premises, the figure and mood will become apparent and the rules can be applied. The statement, for instance, was frequently made:

‘Prohibition should be repealed, because it does the nation more harm than good.’ This implies a complete syllogism which may be formulated as follows:

A law which does the nation more harm than good
should be repealed;
Prohibition is a law which does the nation more harm
than good;
Ergo, Prohibition should be repealed.

Sometimes the causal syllogism is expressed in a manner which seems to involve an obvious four-term construction, thereby violating the First General Rule of the syllogism. Upon closer inspection, however, it will be noticed that one of the terms is merely given as an example of the principle enunciated. For instance:

The pauper is miserable, because he has not the
necessaries of life;
But the miser has not the necessaries of life;
Ergo, the miser is miserable.

Here there are apparently four terms. The middle term is without question ‘one who has not the necessaries of life.’ But that would give us three extremes: ‘pauper,’ ‘miserable,’ and miser.’ However, in the major premise the

word 'pauper is taken as a concrete illustration of the general statement that everyone who has not the necessities of life is miserable'; that part of the general statement can, therefore, be omitted without harming the meaning intended. The real syllogism could just as well be worded:

Everyone who has not the necessities of life is
miserable;
The miser, like the pauper, has not the necessities of
life;
Ergo, the miser, like the pauper, is miserable.

Considered, then, not from the standpoint of grammatical construction, but from the standpoint of logical intention, this sort of reasoning is perfectly legitimate. As long as a mere change of phrasing will produce a valid conclusion, the argumentation should be allowed to stand.

The comparative proposition will cause little difficulty. If the comparative term is part of a complex term, one should see that it is not separated from this complex term, but remains an integral part of it.

The spirit is more important than the body;
The soul of man is a spirit;
Ergo, the soul of man is more important than the
body.

No inorganic being is as noble as a spirit;
But the whole physical world is inorganic;
Ergo, the whole physical world is not as noble as a
spirit.

COVERTLY MULTIPLE SYLLOGISMS

While the overtly multiple premises are comparatively easy of solution, the *covertly multiple premises* present real difficulties. Some of these syllogisms are quite puzzling and require careful analysis. Since the multiple character of these propositions is hidden beneath some innocent looking word or phrase, a surreptitious violation of the rules of consistency may at times creep into the syllogism and vitiate the process of reasoning without detection, unless we are aware of the danger. This is particularly true when one of the component sentences contains a negation, while the other contains an affirmation. In these types, therefore, it is practically necessary to resolve the proposition into its 'exponents' and make distinct syllogisms for each. There are as many varieties of syllogisms on this score as there are types of 'exponibles.'

The syllogisms containing one or more *exclusive* propositions are particularly tricky. The exclusive sentence manifests itself by some word like 'only,' 'alone,' 'none but,' and 'solely.' This type should always be resolved into its component sentences, and each part should be investigated according to figure and mood; only in this way will fallacies be avoided. Consider the following argumentation:

The eternal lives forever;
 Only God is eternal;
 Ergo, only God lives forever.

Is this a legitimate conclusion? It certainly seems valid. It would be perfectly correct, if the syllogism read:

The eternal lives forever;
 God is eternal;
 Ergo, God lives forever.

The one element of doubt engendered in the mind lies in the little word 'only.' Does this apparently harmless word make any difference in the first conclusion? It would not seem so. But let us resolve the minor premise 'only God is eternal' and construct a double syllogism from the resulting two propositions. The minor premise implies two things: 'God is eternal, and everything else is not eternal.' Here is the double syllogism:

<i>First syllogism:</i>		<i>Second syllogism:</i>	
<u>The eternal lives forever</u>		<u>the eternal lives forever;</u>	
<u>God is eternal;</u>	and	<u>what is not God is not eternal;</u>	
Ergo, God lives forever,	and	what is not God does not live forever.	
Ergo, only God lives forever.			
$uM + pP$		$uM + pP$	
<u>$uS + pM$</u>		<u>$uS - uM$</u>	
$uS + pP$		$uS - uP$	
(valid)		(invalid)	

Now examine the result. The first syllogism follows the First Figure, and its rule demands: 'The minor premise must be affirmative, and the major premise must be universal.' The rule is carried out to the letter in the first syllogism, and there is no *flaw* in its consistency. How about the second syllogism, constructed, with the proposition implied in the term 'only'? This, too, is a syllogism of the First Figure, and it must also obey the rule of this figure: 'The minor premise must be affirmative.' But in this second syllogism the minor premise is *negative*: 'What is not God *is not* eternal.' This necessitates a negative conclusion with a universal major term (because it is the predicate of a negative sentence), while in the major premise the major term is particular (because it is the predicate of an affirmative sentence); and so we find an 'illicit major' in the conclusion. Hence, the second syllogism is devoid of consistency; the conclusion is invalid. The original conclusion, therefore, that '*only* God lives forever,' cannot be drawn with consistency from the premises; the word 'only' must be omitted, in the conclusion, so that the original syllogism will read:

The eternal lives forever;
Only God is eternal;
Ergo, God lives forever.

It would be a totally different syllogism, if both premises contain an exclusive proposition. Examine this:

Only the uncreated is eternal;
 Only God is uncreated;
 Ergo, only God is eternal.

Each of these propositions contains two hidden statements. The major premise is composed of these two: 'The uncreated is eternal, and everything created is not eternal.' The minor premise consists of these two: 'God is uncreated, and whatever is not God is created.' Now we are ready to formulate the double syllogism:

<i>First syllogism:</i>		<i>Second syllogism:</i>
<u>The uncreated is eternal;</u>	and	<u>everything created is not eternal;</u>
<u>God is uncreated;</u>	and	<u>whatever is not God is created;</u>
Ergo, God is eternal;	and	whatever is not God is not eternal.
Ergo, only God is eternal.		
uM + pP		uM - uP
<u>uS + pM</u>		<u>uS + pM</u>
uS + pP		uS - uP
(valid)		(valid)

Upon examination, we find that both syllogisms follow the first syllogistic figure, the rule of which demands: 'The minor premise must be affirmative, and the major premise must be universal.' Applying this rule to the two syllogisms, we see that in both cases the minor premise is affirmative and the major premise is universal. In the second syllogism we have a negative conclusion; but this does not involve an 'illicit major,' because the major term is also a universal term in the major premise, because it is the predicate of a negative sentence there also. Hence, both syllogisms and their conclusions are valid; and so we are entitled to

combine the conclusion of the first syllogism ('God is eternal') with the conclusion of the second syllogism ('and whatever is not God is not eternal') and form a single exclusive proposition from both: 'Only God is eternal.' The original syllogism, as given, is therefore a valid and legitimate argumentation.

Now consider this syllogism:

Only God is eternal;
But the world is not God;
Ergo, the world is not eternal.

Here we have a First Figure, and its rule demands that 'the minor premise must be affirmative.' On the face of it, the syllogism violates this rule, because the minor premise ('The world is not God') is not affirmative but negative. That this is really the 'minor' premise, is clear from the fact that the subject of the conclusion ('the world'), which is always the minor term, is also the subject of this premise. We have a negative conclusion, with a universal major term there, which is a particular term in the major premise: an obvious 'illicit major' in the conclusion. So it would seem. However, the major premise is an exclusive proposition containing two component statements: 'God is eternal, and whatever is not God is not eternal.' Constructing a syllogism on the last of these two propositions, we obtain the following result:

God is eternal;	and	whatever is not God is not eternal; The world is something which is not God; Ergo, the world is not eternal.
-----------------	-----	--

$uM - uP$
 $\frac{uS + pM}{uS - uP}$
(valid)

There can be no question now that the syllogism is correct. It follows the First Figure, and it obeys the rule of the First Figure which requires that 'the minor premise must be affirmative, and the major premise must be universal.' This double rule is observed, and the conclusion is validly drawn from the premise.

The syllogism simply followed the *hidden* proposition, implied by the exclusive particle 'only,' and a perfectly legitimate argumentation was the result. This shows, however, how carefully the exclusive propositions must be examined, when used as premises, and what logical pitfalls lurk beneath their seemingly innocent words.

The treatment of the *exceptive* proposition in a premise is practically the same as that of the exclusive, because both are patterned along similar lines. The exception mentioned will always contain a partial denial of the main statement expressed, and the danger of an inconsistent conclusion in one of the component sentences is, therefore, ever to be feared. Safety lies here, too, in dissolving the exceptive proposition into its exponents and then formulating a syllogism with each; any hidden fallacy will then come to

the surface. At first glance the following syllogism appears to be perfectly correct:

All wounded members of the squad received a
decoration;
All, except one, were wounded members of the squad;
Ergo, all, except one, were decorated.

A merely superficial reading of this argumentation would hardly detect anything wrong with it. It sounds plausible. It seems natural. However, just what does the major premise really state? It states that 'the wounded members' were decorated. But it states nothing whatever about those of the squad who were not wounded; it does not say that the unwounded did not receive a decoration. The unwounded member may have been the bravest of them all; he may have obtained a decoration for his bravery, if not for a wound. Of course, the original proposition does not say either, that this unwounded member of the *squad* did receive a decoration for bravery: nothing is affirmed or denied of this one member. After this general analysis of the contents of the major premise, let us divide the exceptive proposition of the minor premise into its exponents, construct separate syllogisms with each, examine the results and see whether these results agree with the general observations made above. The minor premise, when resolved, reads: 'All were wounded members of the squad, and one was not a wounded member of the squad.'

<i>First syllogism:</i>		<i>Second syllogism:</i>
All wounded members of the squad received a decoration;		All wounded members of the squad received a decoration
All were wounded members of the squad;	and	One was not a wounded member of the squad;
Ergo, all were decorated,	and	One was not decorated.
Ergo, all, except one, were decorated.		
uM + pP		uM + pP
<u>uS + pM</u>		<u>uS - uM</u>
uS + pP		uS - uP
(valid)		(invalid)

The first syllogism is correct. It follows the First Figure, whose rule it obeys: 'The minor premise must be affirmative, and the major premise must be universal.' The second syllogism also follows the First Figure, but it violates the first part of the rule that 'the minor must be affirmative.' As a result of this violation we have an 'illicit major' in the conclusion. The major term is particular (pP) in the major premise, because it is the predicate of an affirmative sentence; and it is a universal term in the conclusion (uP), because it is the predicate of a negative sentence. This, of course, offends against the Second General Rule. Hence, it is inconsistent to state in the conclusion that 'all, except one, were decorated.' The syllogism does not warrant any conclusion about this one; he may, or he may not, have received a decoration for some other reason than for being wounded. Not only is the final conclusion ('All, except one, were decorated') inconsistent and false, but even the conclusion of the first syllogism ('All were decorated') cannot be allowed to stand as stated. This 'one unwounded member' also belongs to the squad, and he *may* have been decorated for bravery as well as the rest; but he also *may not* have been decorated. We do not know.

Consequently, all we can consistently conclude is that the ‘wounded members were decorated’; that, however, has already been stated in the major premise.

The whole syllogism would be entirely different, if the major premise could be changed into the exclusive proposition ‘*only* the wounded members of the squad received a decoration.’ In this case the major premise would also be multiple in character, and the two exponent propositions would read: ‘All wounded squad members received a decoration, and no unwounded squad members received a decoration.’ A legitimate conclusion could be drawn from this double sentence without any trouble. Both syllogisms will now follow the First Figure and both will be found to obey its rule: ‘The minor premise must be affirmative, and the major premise must be universal.’

On the next page is shown the new double syllogism:

<i>First syllogism:</i>		<i>Second syllogism:</i>	
All squad members who were wounded received <u>a decoration;</u>	and	All squad members who were not wounded, did <u>not receive a decoration;</u>	
All were squad members who were wounded;	and	One was a squad member who was not wounded;	
Ergo, all received a decoration;	and	One did not receive a decoration.	
Ergo, all, except one, received a decoration.			
uM + pP		uM - uP	
<u>uS + pM</u>		<u>uS + pM</u>	
uS±pP		uS - uP	
(valid)		(valid)	

Naturally, we are not allowed to make arbitrary changes in propositions, especially when such changes involve a *different* meaning. We see that here. To change the plain

categorical statement 'All wounded squad members received a decoration' into the exclusive categorical proposition '*Only* the wounded squad members received a decoration' is unwarranted and inadmissible, unless we are aware of the *actual* facts in the case and know that only those who were wounded received a decoration. Then, of course, such a radical alteration of the meaning would be allowed. Ordinarily speaking, we must accept all statements according to their natural meaning; viewed in this light, the original syllogism is incorrect.

As far as the *reduplicative* and *specificative* propositions are concerned, they present no difficulty. One must remember, however, not to allow the reduplicative and specificative phrase to become separated from the term which it qualifies.

The following syllogism is correct:

Man, in as much as he is rational, is a morally free agent;
But a morally free agent is responsible for his actions;
Ergo, man, in as much as he is rational, is responsible for his actions.

In the subjoined syllogism the reduplication has been altered, giving rise to a fallacious conclusion; the error is evident:

Man, as man, is intellectual;
But man is an animal:
Ergo, man, as an animal, is intellectual.

The inceptive and desitive propositions, when used as premises, are hardly capable of introducing a fallacy into a syllogism, since they merely state the time element when something began or ended. The following argumentation shows this plainly:

The World War began in 1914;
But the war in which the Germans were defeated,
 was the World War;
Ergo, the war in which the Germans were defeated,
 began in 1914.

These, then, are the varieties of categorical syllogisms which result from the fact that a complex or modal proposition or a multiple proposition is used as a premise. Some of them are simple enough; others are more complicated and may give rise to inconsistent conclusions. The exclusive and exceptive propositions are the ones most liable to produce inconsistency in the argumentation; they need careful watching. Because a syllogism, containing such a proposition, appears to be correct, is no guarantee that it is correct. Appearances deceive — also in logic.

SUMMARY OF CHAPTER XIV

Since different kinds of categorical propositions may be used as premises, there will be as many varieties of categorical syllogisms as there are varieties of categorical propositions. The *general rule* is: Divide the multiple proposition into its component statements and reduce each part to the standard syllogism according to figure and mood; keep a strict control over the terms, and consider the meaning more than the words; then apply the general and special rules pertaining to the syllogism.

1. In syllogisms using *complex* propositions, the combinations of complex terms should be kept strictly together.

Modal propositions present difficulties, when different 'modes' occur in the premises. This should be avoided. A change of wording will often help to remove confusion.

2. In *overtly* and *covertly multiple* propositions the *general rule* should be observed: In case of doubt, resolve the multiple proposition into its component statements and arrange each into a separate syllogism, testing each syllogism according to the rule of the figure into which it falls. The overtly multiple propositions are five in number.

The *copulative*, *adversative*, and relative propositions present no special difficulties.

The *causal* proposition is an abbreviated syllogism and can be formulated according to figure and mood.

In the comparative proposition the comparative particle should be constantly retained in the complex term to which

it belongs.

3. The *covertly multiple* propositions often present serious difficulties. Here, more than anywhere else, the proposition should be resolved into its exponibles and each constructed into a syllogism, in order to test its consistency.

The *exclusive* proposition with its particle 'only,' and the *exceptive* proposition with its particle 'except,' always involve a hidden sentence which contains some denial of the main statement. They should, therefore, always be resolved and their exponibles tested separately.

The *reduplicative* and *specificative* propositions, when used as premises, are simple enough, provided the reduplicative and specificative phrases are not separated from the terms which they qualify.

The *inceptive* and *desitive* propositions should cause no trouble.

Chapter 15

HYPOTHETICAL SYLLOGISMS

SO FAR THE CATEGORICAL SYLLOGISM HAS COME UNDER consideration. This type of syllogism, as the name implies, is constructed of categorical propositions, and these consist of a direct assertion between the subject and predicate of a sentence. The *hypothetical* propositions are totally different. They do not contain a direct, straightforward assertion of agreement or disagreement between subject and predicate. *They express the dependence of the truth or falsity of one statement upon the truth or falsity of another statement.* The truth of a hypothetical judgment consists in the truth of this dependence, of this logical relation, between the one statement and the other; if this dependence actually exists, the statement is true, and if this dependence does not exist, the statement is false. Thus, when I state, 'If the ice is hard, the skaters will race,' I am not asserting that the 'Ice is hard' or that 'The skaters will race'; I am merely asserting the dependence of the fact of the race on the fact of the hardness of the ice, and if this relation of dependence of the latter on the former actually is as stated, then the judgment as such is true.

It will be evident that a hypothetical proposition readily lends itself as the major premise of a syllogism. If the minor premise can then definitely affirm or deny one part of these connected statements, the conclusion may possibly affirm or deny the other part. A *hypothetical syllogism*, then, is a syllogism *in which a hypothetical proposition occurs as the major premise*. Obviously, there will be as many types of hypothetical syllogisms as there are types of hypothetical propositions, and these are three in number: conditional, disjunctive, and conjunctive.

CONDITIONAL SYLLOGISMS

The *conditional hypothetical* syllogism is defined as a syllogism *which contains a conditional proposition as the major premise*. Some logicians give the name 'hypothetical' exclusively to the 'conditional' syllogism. Names, of course, are of secondary importance; and if anyone insists on identifying the 'conditional' syllogism with the 'hypothetical' syllogism, there is little sense in quarreling about a mere point of nomenclature. However, the term 'hypothetical,' used in its common meaning of 'problematical,' is wider in significance than 'conditional.' All three types of propositions (conditional, disjunctive, and conjunctive) agree in this one feature that they are problematical in character; none of them makes a direct assertion, involving an act of the mind expressing an outright agreement or disagreement between two ideas. Consequently, there should be some generic term covering and designating all three. The term 'hypothetical,' in the sense of

‘problematical,’ seems to be the best for this purpose, and its meaning is thus used in this connection.

Conditional propositions are ‘if’ statements. There are two parts to such propositions. The first part contains the *condition* and is introduced by the particle ‘if’; the truth of the second part depends on the *fulfillment of the condition* expressed in the first part. Only when the first part, or antecedent, is true, can the truth of the second part, or consequent, also be stated. The antecedent gives the ground, the reason, the cause; the consequent gives the result, the dependent, the effect. This is the logical sequence of ideas in every conditional proposition.

If a syllogism, both in its premise and in its conclusion, consists entirely of conditional propositions, it is a *pure* conditional syllogism; but if one of the premises is a conditional proposition and the other a categorical proposition, it is a *mixed* conditional syllogism. An example of each follows:

Pure conditional syllogism:

If a vertebrate is a mammal, it is no fish;
If a whale suckles its young, it is a mammal;
Ergo, if a whale suckles its young, it is no fish.

Mixed conditional syllogism:

If a whale suckles its young, it is no fish;
The whale suckles its young;
Ergo, the whale is no fish.

Consider these two argumentations. It will be noticed that in the pure conditional syllogism the conclusion is also a conditional proposition; it does not render a conclusion which makes a clear-cut statement of agreement or disagreement between two ideas. The whole argumentation, from beginning to end, is problematical and leads to no definite result, as far as truth and knowledge are concerned. In the example given above, we arrive at a conclusion which does not settle the question whether the whale is a fish or a mammal. On the other hand, the mixed conditional syllogism leads to a definite assertoric decision, as we see in the second example. Truth and falsity are present in categorical statements only, and every conclusion should, therefore, be a categorical proposition. Since the mixed conditional syllogism ends in a categorical proposition for its conclusion, it is a logical instrument of reasoning, capable of advancing truth and knowledge. Nothing further need be said, then, of the pure conditional syllogism; at best its value consists in suggesting a line of thought which may assist the mind in formulating a mixed or conditional-categorical syllogism.

The mixed *conditional-categorical* syllogism, then, has this characteristic that the major premise is a conditional proposition, while the minor premise and the conclusion are categorical propositions. The logical relation between the two premises is such that the *major* premise enunciates a *general principle*, which principle the minor premise *applies to the case in question*. The major premise states positively that the consequent will necessarily follow, *provided* the condition expressed in the antecedent is

fulfilled. The minor premise will state one of two things: it will either state that the condition is fulfilled, and then the conclusion will assert the truth of the consequent; or it will state that the consequent did not follow, and then the conclusion must assert that the condition in the antecedent was not fulfilled.

There are two possible ways of drawing a valid conclusion from the premises in this type: *to accept the antecedent is to accept the consequent; to reject the consequent is to reject the antecedent*. In other words: If I assert that the condition in the antecedent was fulfilled, I must also assert the truth of the consequent, because the truth of the consequent is dependent on the fulfillment of the condition; reversely, if the consequent did not occur, then I know that the condition in the antecedent could not have been fulfilled, otherwise the consequent must also have occurred. Here are two examples which illustrate the point:

Accepting the antecedent:

If he has cancer of the stomach, he is seriously ill;
But he has cancer of the stomach;
Ergo, he is seriously ill.

Rejecting the consequent:

If he has cancer of the stomach, he is seriously ill;
But he is not seriously ill;
Ergo, he has no cancer of the stomach.

Both these syllogisms are valid argumentations. The consequent ('he is seriously ill') depends entirely on the truth of the condition expressed in the antecedent ('if he has cancer of the stomach'). There is the relation of *cause and effect* between the antecedent and the consequent: if the cause has operated ('he has cancer'), then the effect must follow ('he is seriously ill'); and if the effect did not follow ('he is not seriously ill'), then the cause did not operate ('he has *no* cancer'). From this we deduce the double principle: From the truth of the antecedent follows the truth of the consequent; and from the falsity of the consequent follows the falsity of the antecedent.

This leads us to the question: If we reject the antecedent, must we reject the consequent? And if we accept the consequent, must we accept the antecedent? In the two subjoined syllogisms this is done:

Rejecting the antecedent:

If he has cancer of the stomach, he is seriously ill;
He has no cancer of the stomach;
Ergo, he is not seriously ill.

Accepting the consequent:

If he has cancer of the stomach, he is seriously ill;
He is seriously ill;
Ergo, he has cancer of the stomach.

It takes but little thought to realize that these syllogisms are not valid. The mere fact that 'he has no cancer' does not

warrant the conclusion that 'he is not seriously ill' he may be seriously ill from any other dangerous disease, even if 'he has no cancer,' because he may have acute appendicitis, typhoid fever, or something similar. For the same reason, the conclusion of the second syllogism is inconsistent. The fact that 'he is seriously ill' need not have as its cause that 'he has cancer of the stomach'; the cause could be some other disease. The reason is obvious. It is certainly true: '*If* he has cancer of the stomach, he is seriously ill'; this particular cause will assuredly produce this particular effect. But the reverse does not necessarily follow: '*If* he is seriously ill, he must have cancer of the stomach'; this particular effect may be produced by some other cause also. Similarly, the fact that 'He has no cancer of the stomach' will not exclude the possibility that 'He may be seriously ill' from some cause other than cancer. The conditional proposition merely gives *one of the possibly many causes which might produce the same effect*, and it would be inconsistent to exclude all these others as causes, since there is nothing in the antecedent to restrict this effect ('being seriously ill') to this one single cause ('cancer'). The whole matter under discussion can be illustrated thus:

If he has typhoid fever,...

If he has acute appendicitis,...

If he has advanced tuberculosis,...

If he has arterio-sclerosis,.....}=> then=> He is
seriously ill.

If he has cholera,...

If he has a fractured skull,...
If he has, a cerebral lesion,...
If he has cancer of the stomach....

Here we see why the suggested process of reasoning is fallacious. If we reject the antecedent ('He has cancer of the stomach') and state in the minor premise that 'He has no cancer of the stomach,' we must not necessarily reject the consequent ('He is seriously ill') and conclude that 'He is *not* seriously ill'; because he might be 'seriously ill' from any of the *other* causes, even if 'he has no cancer.' And if we accept the consequent ('He is seriously ill'), it does not necessarily follow that the cause of this serious illness is cancer; any other illness might be the cause of this dangerous state of health. We thus see the truth of this second double principle: to reject the antecedent does not involve the necessity to reject the consequent; and to accept the consequent does not involve the necessity to accept the antecedent. Summing up, we find the *law of the conditional* syllogism to be:

From the truth of the antecedent follows the truth of the consequent; but from the falsity of the antecedent the falsity of the consequent does not follow. From the falsity of the consequent follows the falsity of the antecedent; but from the truth of the consequent the truth of the antecedent does not follow.

This law shows that there are two, and only two, valid moods or modes to the conditional syllogism. If the minor premise accepts or 'posits' the antecedent, the conclusion must accept or 'posit' the consequent. And if the minor

premise rejects or 'sublates' the consequent, the conclusion must reject or 'sublate' the antecedent. No other syllogism of this type is valid. The antecedent and the consequent may both be affirmative sentences; or both may be negative; or the one affirmative and the other negative. When we accept or 'posit' them, we must accept the affirmative as an affirmative and the negative as a negative. When we reject or 'sublate' them, we must change the affirmative into its contradictory negative and the negative into its contradictory affirmative. The mood in which the minor premise 'posits' the antecedent and the conclusion 'posits' the consequent is called the *constructive mood*; while the mood in which the minor premise 'sublates' the consequent and the conclusion 'sublates' the antecedent is called the *destructive mood*. Each of these two moods can appear in *four forms*: the antecedent and consequent may both be affirmative; the antecedent and consequent may both be negative; the antecedent may be affirmative and the consequent negative; the antecedent may be negative and the consequent affirmative. This gives us four valid forms for the constructive mood and four for the destructive mood.

Constructive Mood:

- | | |
|---|---|
| (1) If it is A, then it is B;
It is A;
Ergo, it is B. | If socialism is a false system, it is dangerous;
It is a false system;
Ergo, socialism is dangerous. |
| (2) If it is A, then it is not B;
It is A;
Ergo, it is not B. | If prohibition produces serious evils, it should not prevail;
It produces serious evils;
Ergo, it should not prevail. |
| (3) If it is not A, then it is B;
It is not A;
Ergo, it is B. | If Christ is not an impostor, Christ is the Son of God
Christ is not an impostor;
Ergo, Christ is the Son of God. |
| (4) If it is not A, then it is not B;
It is not A,
Ergo, it is not B. | If the world is not infinite, it is not eternal;
The world is not infinite;
Ergo, it is not eternal. |

Destructive Mood:

Destructive Mood:

- | | |
|---|--|
| (1) If it is A, then it is B;
It is not B;
Ergo, it is not A. | If this novel is real art, it is ennobling;
It is not ennobling;
Ergo, it is not real art. |
| (2) If it is A, it is not B;
It is B (i.e., it is not not B);
Ergo, it is not A. | If the soul is a material substance, none of its acts are spiritual;
Some of its acts are spiritual;
Ergo, the soul is immaterial. |
| (3) If it is not A, it is B;
It is not B;
Ergo, it is A.
(i.e., it is not not A) | If life is not created, it existed forever;
Life did not exist forever;
Ergo, it is created. |
| (4) If it is not A, it is not B;
It is B (i.e., it is not not B);
Ergo, it is A
(i.e., it is not not A). | If man is not morally free, he is not morally responsible;
Man is morally responsible;
Ergo, man is morally free. |

The constructive and destructive moods, as illustrated above, are then the only valid forms of the conditional-categorical syllogism: the truth of the antecedent involves the truth of the consequent, and the falsity of the consequent involves the falsity of the antecedent. Inconsistency, with the possibility of error, enters into this type of argumentation, when we attempt to conclude from the falsity of the antecedent to the falsity of the consequent, or from the truth of the consequent to the truth of the antecedent. The very idea and nature of the conditional-categorical syllogism will not allow such a method of inference. The *fallacy* contained in this illicit procedure is, however, a very common occurrence and the prolific source of errors. The following argumentation, though true enough, is not a consistent form of inference:

If a communist is not a patriot, he is a traitor;
He is a traitor;
Ergo, he is not a patriot.

We cannot draw a legitimate conclusion by passing in this way from the consequent to the antecedent. It is bad logic. Though true in some cases, it is not true in all cases; we cannot, therefore, be sure of our conclusions. Take this syllogism:

If a book has artistic merit, it will be widely read;
This book is widely read;
Ergo, it has artistic merit.

This judgment on books is met with quite frequently; but it is fallacious. A book may be widely read for other reasons than 'artistic merit.' It may be a book of intense historical or political interest, without any particular artistic merit; it may be a mere textbook on biology or astronomy or philosophy or relativity or what not; it may be a prurient novel on some morbid or salacious subject, with a strong appeal to primitive passion: the fact of its being 'widely read' does not give us any information about its 'artistic merit.' A similar fallacy, one which has created immense havoc in educated circles, is the plausible and seemingly legitimate inference:

If evolution took place, we must find a gradual transition from the simpler to the more complicated structures of life in the fossil remains of the earth, together with a definite homological plan for all animals and plants;

But this is precisely what we find in nature;
Ergo, evolution took place.

This conclusion does not follow. The result contained in the consequent will be the effect of either one of two causes: creation or evolution. Hence, the mere fact that the consequent is true does not prove that evolution is the cause; it may be, but it need not be, because it may be the result of creation just as well.

The same sort of fallacy occurs, when we sublate the antecedent in the minor premise and then proceed to sublate the consequent in the conclusion. The following syllogism is fallacious:

If there is progress, there is change;
There is no progress;
Ergo, there is no change.

Even if there is no progress, there may be change. Change may go in two directions, toward progress and toward deterioration. Hence, the fact that progress has ceased does not necessarily preclude the possibility of a continued change in the opposite direction. The above syllogism is no better than the following: 'If it rained, the grass is wet; it did not rain; ergo, the grass is not wet.' It may have been sprinkled with a hose. There are, therefore, only two legitimate ways to draw a consistent conclusion in the conditional- categorical syllogism: to posit the antecedent or to sublate the consequent.

DISJUNCTIVE SYLLOGISMS

The *disjunctive* syllogism is relatively simple. It is one whose *major premise consists of a disjunctive proposition*. A disjunctive proposition, as we know, is an 'either — or' statement: 'The sun is either shining or not shining.' Care must be taken to distinguish clearly between the proper and the improper disjunctive propositions, because the significance of these two types is totally different and produces two distinct kinds of syllogisms.

It is characteristic of the proper disjunction that its component parts can *neither be true nor false together*. If this disjunction consists of only two components, the matter presents no difficulty. The general rule, then, will be: *if one*

is true, the other must be false; and if one is false, the other must be true. As a result of this general rule the two-part disjunctive syllogism will have two valid moods: if one part is posited in the minor premise, the other part must be sublated in the conclusion; and if one part is sublated in the minor premise, the other part must be posited in the conclusion. And since both components may be affirmative, or both negative, or the first affirmative and the second negative, or the first negative and the second affirmative, we can readily see that the positing mood and the sublating mood may each appear in four possible forms.

The *positing* twopart proper disjunction:

- | | |
|---|---|
| (1) It is either A or B;
It is A;
Ergo, it is not B. | This criminal is either sane or insane;
He is sane;
Ergo, he is not insane |
| (2) It is either A or not B;
It is A;
Ergo, it is B
(i.e., it is not not B). | The depression is either man-made or not controllable;
It is man-made;
Ergo, the depression is controllable. |
| (3) It is either not A or B;
It is not A;
Ergo, it is not B. | The soul is either not material or mortal;
It is not material;
Ergo, it is not mortal. |
| (4) It is either not A or not B;
It is not A;
Ergo, it is B (i.e., it is not not B). | Either the world is not self-sufficient or not created;
The world is not self-sufficient;
Ergo, the world is created. |

The *sublating* two-part proper disjunction:

- | | |
|---|---|
| (1) It is either A or B;
It is not A;
Ergo, it is B. | The will of man is either determined or free;
It is not determined
Ergo, it is free. |
| (2) It is either A or not B;
It is not A;
Ergo, it is not B. | Man is either a brute or not a descendant of the ape;
Man is not a brute;
Ergo, he is not a descendant of the ape. |
| (3) It is either not A or B;

It is A (i.e., it is not not A);
Ergo, it is B. | The existence of God either cannot be proved or it is
certain;
It can be proved;
Ergo, it is certain. |
| (4) It is either not A or not B;

It is A (i.e., it is not not A);
Ergo, it is not B. | Morality is either not of divine origin or not a matter of
convention;
Morality is of divine origin;
Ergo, morality is not a matter of convention. |

It will be noticed in this type of syllogism, as in the conditional syllogism, that if one part is 'posited,' it must be 'posited' *just as it stands*, whether affirmative or negative; the part that is 'sublated' must be turned into the contradictory of the original, so that the affirmative part is changed into its contradictory negative and the negative part into its contradictory affirmative. To fail to follow this

essential rule would make us guilty of *fallacy*. A careful scrutiny of the syllogisms given above will show plainly how this rule is carried out. With a strict adherence to this rule, the two-part proper disjunctive syllogism should not cause undue difficulty.

When a proper disjunctive proposition consists of *more than two component parts*, the matter is somewhat different. Here, too, only one part can be true, and all the others must be false. Hence, if one component part is posited, all the other parts must be sublated by using the particles 'neither — nor.' For instance:

It is either spring or summer or autumn or winter;
It is winter now;
Ergo, it is neither spring nor summer nor autumn.

But if one of these component parts is sublated, the remaining parts must be posited by means of another disjunction, using again an 'either — or' proposition. One must continue in this way, until one has reached a two-part disjunction for a last syllogism; and this last syllogism will then follow the rule of the two-part proper disjunctive syllogism as explained above. Taking the example given, the procedure will be as follows:

It is either spring or summer or autumn or winter;
It is not spring;
Ergo, it is either summer or autumn or winter.

It is either summer or autumn or winter;
It is not summer;
Ergo, it is either autumn or winter.

It is either autumn or winter;
It is not autumn;
Ergo, it is winter.

The nature of the *improper disjunctive* proposition is quite at variance with that of the proper disjunctive statement, in as much as the members of the improper disjunction are *not mutually exclusive*. It is characteristic of this type that all cannot be false, but some or all may be true together. Hence, if one member of the disjunction is posited, we are not entitled to sublate the other; this would be fallacious, because the others may also be true. But if one member is sublated in the minor premise, the other members must again be *posited with an improper disjunction*. This is the only legitimate conclusion that can be drawn. Here is an example:

In attempting to abolish the depression, President
Roosevelt is influenced by motives either of fame
or of personal profit or of love of humanity or of
patriotism;
His motive is not personal profit;
Ergo, he is influenced by motives either of fame or of
love of humanity or of patriotism.

Naturally, if we know all the facts in the case and are able by a process of elimination to sublate one member after the other, until only one member is left, then the final conclusion will legitimately posit this one remaining member. The following conclusion would thus be correct:

Roosevelt is motivated neither by fame nor by
personal profit nor by love of humanity;
Ergo, he is influenced by motives of patriotism.

In the disjunctive syllogism, therefore, we must first be clear in our own mind whether the disjunction is proper or improper. Each has its own peculiarity and implication. To treat them alike would be a serious logical error which cannot but lead to fallacies. Once the nature of these two forms of disjunction is correctly understood, the rules are simple and the application easy.

CONJUNCTIVE SYLLOGISMS

The *conjunctive syllogism* presents the least difficulties among the hypothetical syllogisms. The conjunctive proposition in the major premise states that two or more things are impossible at the same time. It lies in the nature of this statement that no two of the conjunctive members can be true at the same time; but they may all, for that matter, be false together.

Hence the general rule: *from the truth of one member follows the falsity of the others; but from the falsity of one member the truth of the other (or others) does not follow.*

Supposing we have the statement: 'This thing cannot be a plant and an animal at the same time.' If we are able to make the further statement that 'It is an animal,' then we are certainly correct in concluding that 'It is not a plant.' But if we state that 'It is not an animal,' we cannot necessarily conclude that 'It is a plant,' because the thing may be neither an animal nor a plant, but merely a stone or a dab of mud or anything else. Similarly, if we state that 'It is not a plant,' we are not warranted to state in our conclusion that 'It is an animal,' for the same reason. It is only when we are able to *posit* one member that we can sublate the other; but the nature of a conjunctive proposition does not entitle us, when sublating one member, to posit the other (or others), because they may all be false together. The only valid mood, therefore, in the conjunctive syllogism, is the following:

If the minor premise posits one member of the conjunctive major premise, the conclusion must sublate the other (or others).

It cannot be night and twilight and day at the same
time;

But it is day;

Ergo, it is not night or twilight.

He cannot have been in Chicago and in New York at
the same time;

He was in New York;

Ergo, he was not in Chicago.

A man cannot be guilty and innocent at the same
time;
But he is innocent;
Ergo, he is not guilty.

Fallacies will creep into this type of syllogism, when we sublate a member of the conjunctive major premise and then posit the other member (or members) in the conclusion. This would be the case in the second of the three syllogisms given, if the minor premise stated that 'He was not in New York at the time,' and the conclusion then proceeded with the assertion that 'He must therefore have been in Chicago.' That would not necessarily follow; he *may* have been in Chicago, but there are a thousand other places besides Chicago, in any of which he may have been at the time.

This type of syllogism is very frequently used in criminal court cases, in order to establish an alibi for defendants. The argument will run as follows:

This murder was committed in Chicago;
But he was in New York at the time;
Ergo, the defendant did not commit the murder.

If the prosecutor merely attempted to break down this alibi by proving that 'The accused was not in New York at the time,' that would not automatically place the accused in Chicago; the prosecutor would still have to procure evidence which would undeniably place the accused at the seat of the crime. If he can procure this evidence and also

disprove the alibi, then he is on a fair way to establish the guilt of the accused.

The only consistent argumentation, therefore; based on a conjunctive proposition, is the one in which the *minor premise posits* one of the conjunctive members and the *conclusion sublates* the other (or others). Of course, if the conjunctive statement consists of two members which are the *contradictories* of each other, then it would be a legitimate inference to sublate the one in the minor premise and posit the other in the conclusion; but this is due to the fact that such a proposition is equivalent to a two-part disjunctive proposition, and not because of the nature of the conjunctive statement as such. The third example in the three syllogisms given above would be a case in point. 'Guilty' and 'innocent' are mutually exclusive. To say that 'A man cannot be guilty and innocent at the same time' is equivalent to saying that 'A man is either guilty or innocent'; and the one member is the contradictory of the other. Here it would be permissible, therefore, to sublate the one member in the minor premise and posit the other member in the conclusion. We can readily see, however, that we cannot change every conjunctive statement into a two-part proper disjunctive proposition. Thus, while it is perfectly true to assert that 'A man cannot be in New York and Chicago at the same time,' we cannot arbitrarily assert on that account that 'A man is either in New York or in Chicago.' Hence, the rule of the conjunctive syllogism must stand: the only legitimate mood for a consistent conclusion is *to posit one member in the minor premise and sub/ate*

the other (or others) in the conclusion. No other procedure will insure consistency in this form of argumentation.

These, then, are the three types of syllogisms based on a hypothetical proposition: the conditional, disjunctive, and conjunctive syllogisms. And these, together with the categorical syllogisms, are the various *forms of deduction* which the mind uses in its reasoning. In every instance the intellect begins with some sort of general principle and then applies this principle to the case in hand, passing from the generic to the specific, from the universal to the particular, from the whole to the part.

SUMMARY OF CHAPTER XV

A *hypothetical* syllogism is one which uses a hypothetical proposition as a major premise. There are three types: conditional, disjunctive, and conjunctive.

1. The conditional syllogism contains a *conditional proposition as the major premise*. There are two component members to a conditional proposition: the antecedent, which expresses the condition ('if'); and the consequent, which expresses the result of the fulfillment of the condition.

If the entire syllogism consists of conditional propositions, it is a pure conditional syllogism; if the major premise is a conditional statement and the minor premise and conclusion are categorical statements, it is a *mixed or conditional-categorical syllogism*. The latter alone is of real value for truth and knowledge, and its *general law* reads: From the truth of the antecedent follows the truth of the consequent, but from the falsity of the antecedent the falsity of the consequent does not follow; from the falsity of the consequent follows the falsity of the antecedent, but from the truth of the consequent the truth of the antecedent does not follow.

There are, therefore, only *two valid moods* to the conditional-categorical syllogism: if the minor premise posits the antecedent, the conclusion must posit the consequent; and if the minor premise sublates the consequent, the conclusion must sublate the antecedent.

The former is the constructive and the latter is the *destructive mood*.

2. The *disjunctive* syllogism has a *disjunctive proposition for its major premise*. This type appears in two forms, depending on the fact whether the proposition contains a proper or an improper disjunction.

In the *two-part proper* disjunction the rule is: if one part is true, the other is false; and if one part is false, the other is true. Hence, there are two valid moods: if the minor premise posits one part, the conclusion must sublate the other; and if the minor premise sublates one part, the conclusion must posit the other.

In the proper disjunction which contains *more than two parts*, only one part can be true; the others must all be false. Hence, if the minor premise posits one of these parts, the conclusion must sublate all the others. But if the minor premise sublates one part, the conclusion must posit the others by means of another proper disjunction; and this process of elimination must continue until only two of the original members are left, and these two members will then follow the rule of the two-part proper disjunctive syllogism.

The *improper* disjunction is different. Here all the parts cannot be false, but all may be true together. The only valid *mood*, therefore, is: if the minor premise sublates one member, the conclusion must posit the others with another improper disjunction.

3. The *conjunctive* syllogism, having a *conjunctive proposition for its major premise*, has as its general rule: from the truth of one member follows the falsity of the others; but from the falsity of one member the truth of the

other (or others) does not follow. Consequently, it has *one valid mood*: if the minor premise posits one member, the conclusion must sublate the other (or others).

Chapter 16

VARIATIONS OF THE SYLLOGISM

THE MIND OF MAN IS NOT A MECHANICAL, INSTRUMENT OF reasoning. Were it such, it would undoubtedly cast its deductive reasoning processes in the rigid and stereotyped form of the syllogistic pattern in every instance of argumentation. We would then have nothing but various types of syllogisms with one major premise, one minor premise, and a conclusion, as we observe them in books on logic. But the mind is a living reality, and its functioning is anything but mechanical. Like all living things, it abhors the fixity of movement so characteristic of material appliances and works in the looser and more supple fashion of a self-determining being. In books, magazines, and conversations we seldom meet with a strict syllogistic figure. Deductive arguments are formulated in a free and easygoing manner, with many omissions and additions, which make them deviate from the standardized form. Of course, the basic elements are always present, and all these abridged or amplified variations of the regular method of argumentation can be reduced to the strictly logical process of the syllogism. The laws of consistency are the same, and each argument, no matter in what garb it

appears, must conform to them. We will now consider some of the variations of the standard syllogisms. They are the enthymeme, epichireme, polysyllogism, sorites, and the dilemma.

THE ENTHYMEME

The *enthymeme* is an abridged syllogism in which *one of the premises or the conclusion is omitted*. In most cases, this is the form in which a syllogistic discourse appears in ordinary conversation or writing, since the mind finds it comparatively easy to supply the missing proposition and follow the logical trend of thought. A fallacy, of course, may lurk in the suppressed proposition, and it will be good to test the validity of the argumentation by supplying the missing member and then examining the syllogism according to the rules of the figure to which it belongs.

Every *categorical* syllogism, as we know, has three distinct terms, and each of these occurs twice in the course of the premises and conclusion; the middle term is used twice in the premises, and the major and minor terms are used once in the premises and once in the *conclusion*. This enables us to reconstruct the syllogism without much trouble. If the enthymeme, then, consists of two categorical propositions containing three, and only three, terms, we know that it is an abridged categorical syllogism. As a rule, the tenor of the propositions or the words 'therefore,' 'ergo,' 'consequently,' or a similar expression, will manifest the conclusion. Being certain of the conclusion, we are certain of the minor (S) and major (P) terms. If the

remaining proposition contains the comparison of the minor (S) term with the middle (M), then the suppressed proposition will be the major premise. And if the remaining proposition contains the major (P) term, then the minor premise is the one omitted.

An example or two will illustrate the matter. Consider this enthymeme: 'Prohibition encourages gangland activities; consequently it should be abolished.' The word 'consequently' indicates the conclusion: 'Prohibition (S) should be abolished (P).' We have discovered two of the three terms, the minor (S, 'prohibition') and the major (P, 'should be abolished'). The other sentence must be one of the premises, and it is the minor premise, because the minor term ('prohibition') is compared in it with the middle term (M, 'encourages gangland activities'). The suppressed premise is, therefore, the major premise. It is now possible to reconstruct the complete syllogism, and it will be found to belong to the First Figure.

$(uM + pP)$ – (Any law which encourages gangland activities should be abolished);

$uS + pM$ – Prohibition is a law which encourages gangland activities;

$uS \pm pP$ – Consequently prohibition should be abolished. (valid)

Here is another enthymeme: 'All vices are dishonorable; therefore smoking is no vice.' The last part is the conclusion, with 'smoking' as the minor (S) term and 'vice' as the major (P) term. The term 'dishonorable' must be the

middle (M). Since the major term (P, 'vice') is compared with the middle term (M, 'dishonorable'), the first sentence is the major premise, and the minor premise is omitted. This will be found to be a syllogism of the Second Figure:

uP + pM – All vices are dishonorable;
(uS - uM) – (Smoking is not dishonorable);
uS - uP – Therefore smoking is no vice. (valid)

Now consider the following enthymeme: 'No government based on principles contrary to human nature can survive permanently; but that is the case with the Soviet (i.e., the Soviet is a government based on principles contrary to human nature).' We naturally expect a final judgment: 'Ergo, it can— not survive permanently.' This shows that in this enthymeme the conclusion is missing, while the two premises are given expressly. This again is a syllogism of the First Figure:

uM - uP – No government based on principles contrary to human nature can survive permanently;
uS + pM – But the Soviet is a government based on principles contrary to human nature;
(uS - uP) – (Ergo, the Soviet cannot survive permanently). (*valid*)

That the suppressed premise of a seemingly consistent enthymeme may at times contain a hidden fallacy, can be seen from the following argument: 'Legal interest-taking is not dishonesty; legal interest-taking is therefore no crime.'

The latter portion. of the enthymeme is, of course, the conclusion; the minor (5) term is 'legal interest-taking,' and the major (P) term is 'crime.' Since the minor term ('legal interest') is also found in the given premise, this is the minor premise. Hence, the major premise is omitted. The major premise must read 'All dishonesty is a crime' (and that is obviously the meaning), or it must read 'Some crime is dishonesty.' Common sense forbids us to make it read 'All crimes are dishonesty,' because there are many crimes (murder, for instance) which are not identical with dishonesty; and then, too, 'crime' is the genus to which 'dishonesty' belongs as a species. In any case, the syllogism is inconsistent, whether we say that 'All dishonesty is a crime,' or 'Some crime is dishonesty.'

(uM + pP) – (All dishonesty is a crime);
uS - uM – Legal interest-taking is no dishonesty;
uS – uP – Ergo, legal interest-taking is no crime.

(pP + pM) – (Some crime is dishonesty);
uS - uM – Legal 'interest-taking is no dishonesty;
uS - uP – Ergo, legal interest-taking is no crime.

In the first instance we have a First Figure with an 'illicit major,' because this syllogism violates the rule of the First Figure, which states that 'the minor must be affirmative.' In the second instance we have a Second Figure, also with an 'illicit major,' because the rule of that figure was not carried out which demands that 'one premise must be negative and the major premise must be universal.' Naturally, an

enthymeme may also be an abridged *hypothetical syllogism*. Whenever we encounter an enthymeme with a premise and a conclusion and notice that neither of the terms of the conclusion appears in the premise, then we have a *conditional* syllogism. 'God is the Creator; therefore man is not independent.' This enthymeme is resolved as follows:

If God is the Creator, man is not independent;
God is the Creator;
Ergo, man is not independent.

This does not mean, of course, that the major or minor term of the conclusion may not occur in the premise; it will all depend on the conditional proposition. For instance: 'God is the Creator; ergo, God is man's master.' Here the minor term 'God' occurs both in the conclusion and in the premise, because the major premise will read: 'If God is the Creator, God is man's master.'

Enthymemes may also be abridged *disjunctive* and *conjunctive* syllogisms. The former will appear in the following form:

'He is not orthodox; ergo, he is heretical.' The missing major premise reads: 'He is either orthodox or heretical.' And this is an example of the latter: 'He was in New York all day last Monday; hence, he could not be in Chicago at the same time.' The missing major premise is clear: 'He could not be all day last Monday in New York and in Chicago at the same time.' These types need no further explanation.

THE EPICHIREME

The *epichireme* is a syllogism in which the *proof is conjoined to one or more premises*. In the following epichereme the proof of the statement is added to each of the premises; the word 'because' introduces the proof.

Man has a spiritual soul, because his soul can think;
But a spiritual soul is immortal, because a spiritual
being cannot be dissolved;
Ergo, man has an immortal soul.

Each of the premises, as will be noted, is really an enthymeme. The main proposition is the conclusion, while the clause containing the reason is the premise. Resolving each enthymeme into a standard syllogism, we obtain the following result:

A thinking soul is a spiritual soul,
Man's soul is a thinking soul;
Ergo, man's soul is a spiritual soul.

A spiritual being cannot be dissolved;
Man's soul is a spiritual being;
Ergo, man's soul cannot be dissolved.

A being which cannot be dissolved is immortal;
Man's soul is a being which cannot be dissolved;
Ergo, man's soul is immortal.

THE POLYSYLLOGISM

The preceding argumentation, developed from the epichireme given above, is also an example of a polysyllogism or 'chain of reasoning.' The *polysyllogism* is defined as an argumentation consisting of two or more syllogisms, logically linked together in such a way that the conclusion of the preceding syllogism becomes the premise of the one following. The arrangement of a polysyllogism is plainly visible in the above-mentioned example, and no further comment need be made. The single syllogisms will belong to the standard figures and moods and must, of course, comply in all points with the respective rules which govern them.

THE SORITES

The *sorites* is an abridged polysyllogism, consisting of three or more premises in such a way that *the predicate of the preceding premise becomes the subject of the following premise, the final conclusion being composed of the subject of the first premise and the predicate of the last; or, inversely, it is an abridged polysyllogism in which the subject of the preceding premise becomes the predicate of the following premise, with the conclusion composed of the subject of the last premise and the predicate of the first premise.* As will be noted from this rather lengthy definition, the sorites appears in two distinct forms; the first is called the *Aristotelian*, the second the *Goclenian* sorites. Rudioiphus Goclenius, professor at Marburg, in 1598, was

the first to expound this second type of sorites; hence the name. We can best study the nature and arrangement of these two types by means of letters:

Aristotelian sorites:

A=B - Aristotle is a man;

B=C - All men are mammals;

C=D - All mammals are living beings;

D=E - All living beings are substances;

A=E - Ergo, Aristotle is a substance.

Goclenian sorites:

D=E - One who has no peace of mind is miserable;

C=D - One who lacks much has no peace of mind;

B=C - One who has many desires lacks much;

A=B - One who has many vices has many desires;

A=E - Ergo, one who has many vices is miserable.

There is no essential difference between the Aristotelian and Goclenian sorites; it is merely a matter of arrangement. A glance at the twofold construction illustrated above will show that by inverting the order of the premises an Aristotelian sorites becomes a Goclenian, and vice versa. Both types of sorites follow the First Figure.

Aristotelian sorites:

B=C - All men are mammals;

A=B - Aristotle is a man;

A=C - Ergo, Aristotle is a mammal.

C = D - All mammals are living beings;
A = C - Aristotle is a mammal;
A = D - Ergo, Aristotle is a living being.

D = E - All living beings are substances;
A = D - Aristotle is a living being;
A = E - Ergo, Aristotle is a substance.

Goclenian sorites:

D = E - All living beings are substances;
C = D - All mammals are living beings;
C = E - Ergo, all mammals are substances.

C = E - All mammals are substances;
B = C - All men are mammals;
B = E - Ergo, all men are substances.

B = E - All men are substances;
A = B - Aristotle is a man;
A = E - Ergo, Aristotle is a substance.

There is, of course, no great truth contained in these two resolved sorites. This very simple example was chosen purposely, in order to illustrate the fact that the same premises may be arranged into both types, the Aristotelian and the Goclenian. Both follow the First Figure of the categorical syllogism, and the rules governing the First Figure must be rigidly observed from beginning to end in each of the separate syllogisms into which the sorites can

be resolved. These rules will be upheld in the *Aristotelian* sorites by applying this rule: *no premise may be negative except the last; no premise may be particular except the first.*

If any premise, except the last, were negative, the conclusion would involve an ‘illicit major.’ Every intermediate conclusion in an Aristotelian sorites becomes the *minor* premise of the succeeding syllogism ($A = C$, $A = D$), and the rule of the First Figure demands that ‘the minor premise must be affirmative’; otherwise an ‘illicit major’ will result. The only premise that is not used as a minor premise in the course of the argumentation is the last one ($D = E$); it is the *major* premise of the last syllogism and is, therefore, permitted to be negative, because the rule of the First Figure merely states that the minor premise must be affirmative. If we construct the sorites into syllogisms with letters instead of sentences, the whole matter will be visually clear:

$$\begin{array}{ccc}
 \begin{array}{l} uB + pC \\ \hline uA - uB \\ \hline uA - uC \end{array} & \longrightarrow & \begin{array}{l} uC + pD \\ \hline uA - uC \\ \hline uA - uD \end{array} \\
 & & \longrightarrow \begin{array}{l} uD + pE \\ \hline uA - uD \\ \hline uA - uE \end{array}
 \end{array}$$

All three syllogisms have an ‘illicit major,’ as will be noted, because they violate the rule of the First Figure. The first of these three could be made a valid syllogism by making the major premise negative ($B - C$) and the minor premise-affirmative ($A + B$). But that would not help matters, because the conclusion would still be negative ($A - C$), and this conclusion will become the minor premise in

the second syllogism; thereby an 'illicit major' is introduced into the conclusion of the second syllogism (A - D), vitiating the whole argumentation. Hence, none of the premises may be negative *except the last*. If the last premise is negative, and all the preceding premises are affirmative, the final conclusion will be negative, and the whole sorites will be valid:

The *second part* of the rule for the Aristotelian sorites states that *no premise may be particular except the first*. Here is the reason. The subject of the first premise (A) and the predicate of the last premise (E) are the minor and major terms of the final conclusion. All the other terms (B, C, D) act as middle terms. The preceding diagram shows that each of these middle terms is the subject of the major premise and the predicate of the minor premise in its respective syllogism. As we have just seen, these syllogisms belong to the First Figure, in which the minor premise must be affirmative; the middle term, being the predicate of this affirmative minor premise, will be particular. But this same term is also the subject of the major premise; hence, if any of these major premises (except the first, where A is the subject) were particular propositions, the middle term would also be particular here. And thus the middle term would be twice particular, and that would involve an

undistributed middle; that, of course, would vitiate the sorites. The truth of this can be seen in the following diagram:

$$\frac{\begin{array}{l} pB + pC \\ uA + pB \\ \hline uA + pC \end{array}}{\quad} \longrightarrow \frac{\begin{array}{l} pC + pD \\ uA + pC \\ \hline uA + pD \end{array}}{\quad} \longrightarrow \frac{\begin{array}{l} pD + pE \\ uA + pD \\ \hline uA + pE \end{array}}{\quad}$$

Here we see how an undistributed middle results from making the premises (except the first) particular propositions. Even if we made only one of them particular, the sorites would be consistent no longer; the whole sorites would be invalid. We also see why the first premise ($A = B$) may be particular. The subject of the *first* premise (A) is never used as a middle term, because it is the minor term in the conclusion, and it could therefore be used as a particular term throughout without involving any violation of the rule of the First Figure, which demands that ‘the minor premise must be affirmative and the major premise must be universal.’ From all this we see the necessity of the rule for the Aristotelian sorites: ‘No premise may be negative except the last, and no premise may be particular except the first.’

Since the *Goclenian* sorites contains merely an inverted arrangement of the premises of the Aristotelian sorites, the same rule, but in an inverted order, applies: *no premise may be negative except the first, and no premise may be particular except the last*. As we have just seen, the first premise of the Aristotelian sorites ($A B$) may be particular ($pA \pm pB$); and since this premise is the last one in the

Goclenian sorites, the last premise of the Goclenian sorites may be particular. The last premise of the Aristotelian sorites (D E) may be negative; this being the first premise of the Goclenian sorites, it is obvious that the first premise of the Goclenian sorites may be negative. The other premises occupy the same intermediate position in both types; therefore, they may be neither negative nor particular. Hence the rule.

Occasionally a sorites may seem to consist of categorical propositions, while in reality they do not. The following humorous sorites is a case in point:

High dog tax, less dogs;
Less dogs, more cats;
More cats, less mice;
Less mice, more bumblebees;
More bumblebees, more pollination of clover;
More pollination of clover, more clover seed;
Ergo, high dog tax, more clover seed.

It is only when attempting to resolve a sorites like this into the regular syllogistic form that we realize that we are not dealing with categorical propositions. The line of argumentation is evidently hypothetical in character; we feel that each statement is an 'if' proposition, a conditional sentence. This sorites, therefore, resolves itself into a series of conditional premises:

If the dog tax is high, the number of dogs decreases;

If the number of dogs decreases, the number of cats increases;

If the number of cats increases, the number of mice decreases;

If the number of mice decreases, the number of bumblebees increases;

If the number of bumblebees increases, the pollination of clover increases;

If the pollination of clover increases, there will be more clover seed;

Ergo, if the dog tax is high, there will be more clover seed.

We may, of course, raise many objections as to the truth of the *fact*: mentioned in these conditional premises and thus challenge the *truth* of the final conclusion; but, granted the truth of each statement, the argumentation as such would be *formally valid*. And if we posit the condition of the first premise, namely, 'The dog tax is high,' the final conclusion would consistently follow that 'There will be more clover.' Such a so-rites, naturally, must observe the general rules which govern the conditional-categorical syllogism: 'To posit the antecedent is to posit the consequent, and to sublate the consequent is to sublate the antecedent.'

THE DILEMMA

One of the most interesting types of syllogistic reasoning, as convincing as it is effective, is the *dilemma*. It is defined as

an argument in which the major premise consists of a disjunctive proposition and the minor premise consists of conditional propositions, each of which takes one member of the disjunction and from it draws a conclusion detrimental to the adversary. As far as the structure of the dilemma is concerned, we thus have the following arrangement: the first proposition is a disjunctive statement; the second is a conditional statement; the third is a conditional statement; and the fourth is a conclusion which makes a definite, categorical decision following necessarily from both conditional statements. From a logical standpoint it makes no difference whether the double conditional proposition (the minor premise) or the disjunctive proposition (the major premise) is placed first in the argument; very frequently the minor premise leads off. Here are two examples:

He who speaks disrespectfully of holy things, speaks
either in earnest or in jest.

If he speaks in earnest, he is guilty of blasphemy; if he
speaks in jest, he is guilty of levity.

In either case his conduct is reprehensible.

If God exists, you are wrong in not worshiping Him; if
He does not exist, you are foolish in leading a
moral life.

But God either exists or He does not exist.

Ergo, you are either wrong or you are foolish.

The main force of the argument will depend upon the correct enumeration of the possible members in the disjunction. Where these members are contradictory, there can be no more than two. At times, however, three or four or more members constitute the complete disjunction, and all of them will have to be mentioned. When three members are used, we have a *trilemma*; when four, a *tetralemma*; when more than four, a *polylemma*. But usage sanctions the term 'dilemma' to designate them all. The basic idea, of course, is the same, no matter how many members are included in the disjunctive premise. In order that the dilemma be a consistent form of argumentation, the following rules must be observed:

First Rule: The disjunctive enumeration must be complete. A contradictory disjunction, as has been stated, is the best for the purpose, because there can be no neutral middle ground between them. The adversary cannot escape; he will be gored by one of the two 'horns' of this dilemma. We have a case of this kind in the dilemma of Tertullian against the decree of the Roman Emperor Trajan, which ordered that the Christians should not be sought out, but, if brought before the tribunal, they should be punished. Tertullian argued:

The Christians are either guilty or innocent of crime.

If they are guilty, why should they not be sought, out?

If innocent, why should they be punished when found?

In either case, the decree is unjust.

There is no middle course between 'guilty or innocent of crime'; a person is either the one or the other, and the logic of the two 'horns' of the disjunction is inescapable. But when the dilemma contains an incomplete disjunction, and the adversary avoids the uncomfortable consequences of the disjunction by pointing out that a further possibility has been overlooked which enables him to destroy the consistency of the argument, he is said to 'escape between the horns.' Here is an illustration:

If I am rich, I must worry about losing my wealth; if I
am poor, I must worry about making a living.
But I must be either rich or poor.
Hence, I must always worry.

To this, one can rightly answer: 'You may be neither rich nor poor, but in moderately comfortable circumstances, where there is neither danger of losing great wealth nor danger of starvation; ergo, you have no need to worry.' Here one accepts a third possibility which does not involve the consequences mentioned.

SECOND RULE: THE CONDITIONAL STATEMENTS AND THE GENERAL conclusion drawn from them must really follow with consistency and necessity. The very complexity of the dilemma, which makes it so convincing and effective, if correctly constructed, is the greatest source of danger, because inconsistency may lurk in the incompleteness of the disjunction or in the lack of real cogency in either of the

conditional statements based upon the members of the disjunction. Here is a dilemma that has consistency in all its parts. The Koran of the Mohammedans considers Jesus a true prophet, but not the Son of God; this allows the following dilemma:

Either Christ is a true prophet or He is not.

If He is a true prophet, then He is also the Son of God, because He claims it, and a true prophet cannot lie in such a vital matter; but then the Koran is false, because it denies that He is the Son of God. If He is not a true prophet, then the Koran is false, because it considers Him a true prophet.

Ergo, the Koran is false in either case.

If an adversary can show that the conclusions drawn from the members of the disjunction are not the results of a necessary deduction, but that a person may accept one or both of the alternatives and arrive at an entirely different conclusion, he is said to destroy the argument by 'taking the dilemma by the horns.' This is always the case when a particular cause may have different effects, any of which may result with equal probability; or when different causes may produce the same kind of an effect, so that the particular cause alleged in the dilemma may be denied. As long as one of the 'horns' can be turned against the antagonist, it is sufficient to overthrow the dilemma. Let us suppose that an opponent in the course of controversy makes the following dilemma:

If my adversary were intelligent, he would see the worthlessness of his arguments; if he were honest, he would acknowledge himself wrong.

But either he does not see that his arguments are worthless; or, seeing it, he will not acknowledge himself wrong.

Ergo, he is wanting in intelligence or he is dishonest.

To this one could answer by accepting the first 'horn' and showing that the opposite effect may result: 'Certainly I am intelligent: but that does not necessarily mean that I must recognize my arguments as invalid; on the contrary, just because I am intelligent, I know them to be correct.'

THIRD RULE: THE DILEMMA SHOULD NOT BE OPEN TO A REBUTTAL.

A dilemma is rebutted, when the selfsame disjunctive members are accepted and conclusions are drawn from them which are the very opposite of those made by the opponent. A celebrated instance of the use of the dilemma is 'Empson's fork.' Empson was an agent of King Henry VII, and he devised the following argument to justify the imposition of large fines upon people:

If the accused lives at a small rate, his savings must have made him very rich; if, on the other hand, he maintains a large household, his expenditure proves him to be wealthy.

But he does either the one or the other.

Ergo, he must be very wealthy and can afford to pay a heavy fine into the king's treasury.

Here the mode of living is taken as an indication of wealth; but it does not need much intelligence to realize that the mode of living is not a real index of one's financial status. Empson's dilemma is open to the obvious rebuttal:

If the accused lives at a small rate, his parsimony is an evident sign of poverty; if he maintains a large household, this fact alone must have hindered him from accumulating great wealth.

But he lives either in the' one way or in the other.

Ergo, one way or the other, he is not wealthy and can pay no heavy fine.

Considered closely, the rebuttal in this case is just as faulty as the original dilemma of Empson; the mode of living as described is neither a sign of poverty nor of wealth, because in both modes the accused may be poor or rich or merely in moderate circumstances. But the rebuttal is certainly valid, in as much as it shows that Empson's 'fork' is based on invalid premises, which do not warrant his conclusion; because the opposite conclusion could be drawn with equal right and cogency. And that is all that a rebuttal is supposed to do: prove the inconsistency of the original dilemma.

EXTRA-SYLLOGISTIC INFERENCES

An interesting phase of the process of reasoning is the problem of extra-syllogistic inference. The question refers to certain forms of mediate inference which follow the general line of thought characteristic of the — syllogistic figures, but do not seem to conform to the basic idea of these figures. The essential feature of the figures consists in this that a conclusion is drawn with necessity from two premises in virtue of the *Dictum de omni* and the *Dictum de nullo*: 'What can be affirmed of the logical whole, can be affirmed of every logical part of this whole; and what can be denied of the logical whole, can be denied of every logical part of this whole.'

It is precisely this necessary *relation of logical whole to logical part* which underlies the consistency of the categorical syllogism in its figures. Two ideas are compared with a known middle term; and this comparison is based on the relations of *extension* and *comprehension*, giving rise to a necessary and universal principle in one of the premises, which general principle is then applied to a single or less general case falling under this principle. The mind, by an act of *intuition*, perceives the evident relation of the one idea as a 'logical part' to the other idea as the 'logical whole' and realizes that the comprehension of the major term must be affirmed (or denied) of the minor term in the conclusion because the minor belongs to (or is excluded from) the extension of the major. The whole process of reasoning is such, therefore, that the copula ('is, is not; are, are not') expresses an identity or non-identity of *comprehension* (attributes) between minor, major, and middle terms. This axiom of the *Dictum de omni et nullo*,

though underlying all four syllogistic figures, is best exemplified in the First Figure, as can be seen from the subjoined inference:

All men have power of speech;
The pygmies of Africa are men;
Ergo, the pygmies of Africa have power of speech.

The comprehension of the attribute 'power of speech' is predicated of 'all men.' By means of an analysis of the ideas of man and 'power of speech,' the mind recognizes the fact that 'power of speech' is a necessary and universal attribute of '*man as such*,' and it expresses this fact in the necessary and universal law that 'All men have power of speech.' Then, in virtue of the axiom of the Dictum, the mind perceives the evident truth of the relation of identity between the 'logical whole' ('all men') and the 'logical part' ('the pygmies of Africa'): since the attribute of power of speech' belongs to 'all men,' it must also. belong to 'the pygmies of Africa.' Hence the conclusion.

Now, then, can the mind make valid inferences which follow this general pattern of the categorical syllogistic figures, but are based on the evident truth of an *axiom different from that of the Dictum*? If so, then we have extra-syllogistic inferences. There is no real reason why the mind could not base its inferences on some other evident relation existing between ideas besides that of identity and non-identity. As a matter of fact, the conditional (hypothetical) syllogism is based on the axiom of the antecedent and consequent ('if — then'); and the disjunctive syllogism is

based on the axiom of exclusive alternatives ('either — or'). Of course, these two types are not categorical, but *hypothetical* syllogisms, and they cannot, therefore, be taken as instances of extra-syllogistic *categorical* inferences; but they do show conclusively that the mind can and does make valid inferences based on an axiom different from that of the *Dictum*. There are, however, certain types of inference which follow the general pattern of the categorical syllogism and yet are not deductions based on the relation of identity and diversity as we find it in the syllogistic figures. Here is an example:

Germany is larger than France;
Russia is larger than Germany;
Ergo, Russia is larger than France.

This is undoubtedly a valid argumentation, and it follows the pattern of the categorical syllogism; but it does not conform to the rules of the syllogism, because it contains four terms. 'Germany' is one term; 'larger than France' is another; 'Russia' is the third; and 'larger than Germany' is the fourth. Furthermore, neither the major nor the minor premise contains a necessary and universal law or principle resembling a 'logical whole..'. There is, though, a universal and necessary principle underneath this inference, based on the self-evident relation of *comparative magnitude*. This relation, however, does not express an identity or diversity of attributes between the major and minor term in the conclusion, as we ordinarily find it in the categorical syllogism. Here is a similar example:

7 + 5 equals 12;
20 - 8 equals 12,
Ergo, 7 + 5 equals 20 - 8.

The necessary and universal truth or law, which furnishes the mind with an intuitive insight into the relations existing between the numerical operations mentioned above, is the mathematical axiom which states that 'things which are equal to the same thing are equal to each other.'

Similar relations exist between things which equal, or differ from, each other in *degrees of quality*. These relations of qualitative degrees lend themselves also to extra-syllogistic inferences, as we see in the following illustrations:

Ice is colder than water;
Liquid air is colder than ice;
Ergo, liquid air is colder than water.

An elephant is less powerful than a locomotive;
Man is less powerful than an elephant;
Ergo, man is less powerful than a locomotive.

Mercury is lighter than radium;
Hydrogen is lighter than mercury;
Ergo, hydrogen is lighter than radium.

The relations of time and space can also be utilized as the basis of inferences of this kind. For instance:

Adam was older than Abel;
Methusalem was older than Adam;
Ergo, Methusalem was older than Abel.

H. Hoover was president after C. Coolidge;
F. Roosevelt was president after Hoover;
Ergo, F. Roosevelt was president after C. Coolidge.

New York is east of Toledo;
Chicago is west of Toledo;
Ergo, Chicago is west of New York.

The atmosphere is below the stratosphere;
The atmosphere is above the earth;
Ergo, the earth is below the stratosphere.

A different relation, though partaking of the same character as far as inferential value is concerned, is that of kinship and jurisdictional authority. For example:

Solomon was the father of Roboam;
David was the father of Solomon;
Ergo, David was the grandfather of Roboam.

Albert is the husband of Margaret;
Joseph is the brother of Albert;
Ergo, Joseph is the brother-in-law of Margaret.

The captains are inferior to the colonels;
The general is superior to the colonels;

Ergo, the general is superior to the captains.

These and similar relations form the basis of *extra-syllogistic categorical inferences*. Many logicians will not admit that these inferences of relation should be styled 'extra-syllogistic.' They point to the fact that inferences based on hypothetical propositions are also called 'syllogisms,' although these hypothetical syllogisms follow the well-known figures even to a lesser degree than the ones mentioned here. This is undoubtedly true. But it is equally true that these inferences of relation do not conform to the rules of the standard syllogistic figures; they should, then, not be considered as mere variations of these figures, but should be placed on a par with the categorical and hypothetical syllogisms and be treated with them as a special type of syllogism. After all, it is not the name that counts, but the *principle* on which they rest; and that principle is one of relation and not that of the 'logical part' as contained in the 'logical whole,' as expressed by the *Dictum de omni et nullo*.

This closes our investigation into the nature and the various types of the syllogism, considered as a specific form of reasoning. Just as the mind expresses its judgments in categorical and hypothetical propositions, so it also bases its syllogisms on categorical and hypothetical statements. In every instance the procedure is fundamentally the same: from the comparison of two ideas with a known third it passes to the judgment of the identity or non-identity of the two doubtful ideas among themselves. The conclusions it reaches are, therefore, not a leap into the dark, but a

consistent, coordinated stepping from the known to the unknown, based upon the principle that what is true of the logical whole must be true of every logical part. The syllogism is thus the standard form of one of the main reasoning methods of the mind: deduction.

The other main reasoning method is induction.

SUMMARY OF CHAPTER XVI

Due to the flexibility of the mind, it often deviates from the stereotyped form of the syllogism by the addition or omission of material. This gives rise to some variations of the syllogism.

1. The *enthymeme* is an abridged syllogism in which *one of the premises or the conclusion is omitted*. It should be reconstructed according to type and judged according to the rules of the type.

2. The *epichireme* is a syllogism in which *the proof is conjoined to one or more premises*. Such a premise with proof is really an enthymeme and should be treated like an enthymeme.

3. The *polysyllogism* is an argumentation consisting of *two or more syllogisms, logically linked together in such a way that the conclusion of the preceding syllogism becomes the premise of the one following*.

4. The *sorites* is an *abridged polysyllogism*, in which a number of premises lead to a *common conclusion*. In the *Aristotelian* sorites the predicate of the preceding premise becomes the subject of the following premise, the final conclusion being composed of the subject of the first premise and the predicate of the last. In the *Goclenian* sorites the subject of the preceding premise becomes the predicate of the one following, with the conclusion composed of the subject of the last premise and the predicate of the first premise. The rule for the Aristotelian sorites is: no premise may be negative except the last, and

no premise may be particular except the first. The rule for the Goclenian sorites is: no premise may be negative except the first, and no premise may be particular except the last.

5. The *dilemma* is an argument in which *the major premise consists of a disjunctive proposition and the minor premise consists of conditional propositions, each of which takes one member of the disjunction and from it draws a conclusion detrimental to the adversary*. Three rules must be observed: the disjunctive enumeration must be complete; the conditional statements and the general conclusion must really follow with consistency and necessity; the dilemma must not be open to a rebuttal.

6. *Extra-syllogistic inferences* follow the general pattern of the syllogistic figures, but they are based on principles different from the axiom of the *Dictum de omni et nullo*. Some are based on the *relation of comparative magnitude*; others, on the relation of *degrees of quality*; others, on the relation of *space* and *time*; others on the relation of kinship and jurisdictional authority.

PART IV

INFERENCE AND ARGUMENTATION: INDUCTION

Chapter 17

NATURE OF INDUCTION

KNOWLEDGE IS THE GOAL OF ALL THINKING. AND THE POSSESSION of truth is knowledge. Correct thinking alone can lead us to truth and knowledge. For this reason it is necessary to know the import of ideas, judgments, and inferences. Ideas are united into judgments, and truth is formally and exclusively contained in the judgment. If a mere comparison of ideas would enable the mind to perceive their agreement or disagreement among themselves, the mind would, without any further action, express their identity or non-identity in an affirmative or negative judgment, and thus the mind would pass from truth to truth through an immediate process of thinking. The building of a science and the unification of all sciences into the higher science of philosophy would then be a simple matter. Unfortunately, this is not the case.

FORMAL AND MATERIAL TRUTH IN INFERENCE

It is easy enough for the mind to state that snow is cold and water is a liquid and iron is hard and the sun is luminous and the tree grows and the dog runs and man thinks. The

mind acquires such and similar truths through the process of immediate perception, and they are evident truths of observation. Other truths, axiomatic in character, like the **Principle of Identity**, the **Principle of Contradiction**, the **Principle of Excluded Middle**, are *laws of thought*, and a mere analysis of the ideas of such principles make their truth self-evident to the mind. A further development of these laws of thought shows the self-evident truth of some other universal and necessary principles, as 'The whole is larger than the part,' 'everything must have a sufficient reason,' 'every effect must have a cause,' the '*Dictum de omni et nullo*,' and similar axioms. But the great bulk of scientific truths needs more than immediate observation and an analysis of fundamental ideas; they demand a process of *reasoning* to establish their truth. Science, therefore, cannot be acquired except through an extensive use of the reasoning powers of the mind. This necessitates an accurate knowledge of the different forms of argumentation, in order to insure correct thinking and the avoidance of error, so that the conclusions of these arguments will be valid. These conclusions will be valid, if they are *consistently* drawn from *true* premises. A conclusion will be *consistent* when it flows with strict *logical necessity* from the premises *as given*; and the conclusion will be consistent and true, when it flows with logical necessity from true premises. Only if both these factors are present, will the mind be certain that the concluding judgment expresses truth. Consistency will be present in an argumentation, when the rules governing each type of reasoning are accurately observed. These rules have been

declared and examined and proved in the preceding chapters. They guarantee the *formal* truth of consistency.

But it is not sufficient to have consistency in an inference, in order that the conclusion be true; consistency merely makes the inference correct. No conclusion, no matter how consistently drawn, will be true, unless the premises themselves are true judgments. The two syllogisms which follow are correct according to all the rules of the syllogism and the laws of correct thinking, but one leads to a true and the other to a false conclusion.

All aquatic animals are fishes;
The whale is an aquatic animal;
Ergo, the whale is a fish.

All animals which suckle their young are mammals;
The whale is an animal which suckles its young;
Ergo, the whale is a mammal.

The first conclusion is false, the second is true. Both syllogisms are identical according to figure and rule, and both are consistently drawn from the given premises; both are, therefore, *formally* correct. Then why the difference? Both can evidently not be true at the same time. What is wrong with the first example?. The *material* truth is missing in the major premise of the first example: *it is not true that 'All aquatic animals are fishes,'* and that is why the premises led to a false conclusion. The *formal* truth of an argument consists in the correct *arrangement* of the premises, so that the conclusion must follow with logical

necessity. The material truth of an argument consists in the truth of the premises as *statement of facts*. Both elements are required, material and formal truth, in order that the conclusion be true with certainty. The strict observance of the rules of correct thinking will guarantee the *formal* truth of an inference. But what will guarantee the *material* truth of the premises as statements of facts? For instance, how are we to know whether 'All aquatic animals are fishes' and that 'The whale is an aquatic animal,' or whether 'All animals which suckle their young are mammals' and that 'The whale is an animal which suckles its young'? A mere comparison of the ideas contained in these judgments will never assure us that they are materially true; they are not self-evident truths.

The material truth of all *factual* statements, such as are found in scientific laws, can only be discovered by a close observation and *study of nature* itself. Only when the facts and laws of nature are proved to be true can we be sure that our premises are true. Nature, however, is a very complex and mysterious reality, and a superficial observation of the workings of nature will seldom suffice to wrest her secrets from the tangled web of phenomena. As a rule, the way of the scientist is tedious and laborious. There is no thumb- rule method which can be applied to discover the laws of nature. Each science, due to the peculiarity of its subject matter, has its own characteristic method of discovery and proof. The methods of the mathematician and astronomer will be of little value to the historian and the anthropologist, and the methods of the political economist and educator can hardly be used by the physicist and

chemist. Nevertheless, the laws of thought are the same for all sciences, and the fundamental principles of scientific method must be the same for all sciences, because it is the selfsame human mind which is active in the discovery and proof of truth in all of them. Logic, the science of correct thinking, is not concerned with the peculiarities of scientific method characteristic of the special sciences as such. But it is the province of logic, as the philosophy of correct thinking, to investigate the *fundamental principles of method* which all sciences must use at *all times* and in *every process* of extensive research.

SCIENTIFIC METHODS

Method is defined as *the proper arrangement of our mental processes in the discovery and proof of truth*. There are two fundamental methods: synthesis and analysis. Synthesis proceeds from the simple to the complex, from the general to the special, from the universal to the particular, from the necessary to the contingent, from the 'logical whole' to the 'logical part,' from the principle to the applications of the principle, from the general law to the individual cases, from cause to effect. Synthesis is essentially a method of *deduction*, and the sciences which employ primarily the synthetic method are called the rational or *deductive sciences*. Such is mathematics, which begins with a few fundamental ideas and axioms and, without the aid of observation and experiment, gradually builds up a most profound and complicated science of truths.

Analysis is the reverse of synthesis. It passes from the concrete to the abstract, from the complex to the simple, from the particular to the universal, from the contingent to the necessary, from the applications of a principle to the principle itself, from the phenomena to the underlying general law, from the effect to the cause. This method gives rise to the analytic, experimental, *inductive sciences*. The *physical sciences* use this method of *induction* throughout a great part of their research into the problems of nature.

It would be a serious mistake (one all too frequently made) to think that the natural sciences are *exclusively* analytic or inductive. Astronomy, for instance, uses the deductive principles of mathematics and the inductive method of physics and chemistry in about equal measure. The experimental sciences, after employing induction to discover general laws, use these laws as principles of demonstration for further experiments. On the other hand, mathematics, the most synthetic and deductive of all sciences, must first derive its fundamental ideas of lines, planes, circles, and angles from observation of concrete things. We thus see that analysis and synthesis, deduction and induction, are not opposed, but assist each other in the discovery and proof of truth. Whichever method is the most appropriate under the circumstances, is the proper one to be used. If the *natural sciences* are called inductive, it is due to the fact that their *predominant* method is *induction*.

INDUCTIVE METHOD

Induction is the legitimate inference of universal laws from individual cases. The essential character of induction is identical with the mental process of *abstraction* and *generalization*. As the mind, after contemplating individual things, forms abstract and universal *ideas* of them, so it also formulates abstract and universal laws from individual phenomena. In both cases this is due to an understanding of the *nature* of the reality under observation, not to the fact that the mind has examined every single instance of the phenomena throughout the world.

When scientists declared the general law that water at sea level freezes at +32° Fahrenheit, they did not arrive at this law by taking every bit of water in the world down to sea level and actually freezing it. But in each and every instance observed (and many thousands of experiments were made), it was found that water froze at sea level whenever the temperature dropped to +32° Fahrenheit. Hence, they rightly concluded that it is the *nature* of water to act in this fashion; and since the nature of a thing is the same everywhere, water will *at all times and in all localities* freeze under these identical circumstances: it is a law based on the nature of water as the cause of this effect. Similarly, it is a general physical law that all diamonds are combustible. It was not necessary to actually burn all diamonds in order to establish this law. Some diamonds have actually been destroyed by combustion; and when chemistry discovered the fact that these precious stones consist of nothing but carbon, they readily understood that it was the very nature of the diamonds which made them

combustible: therefore, the law that *all* diamonds are combustible.

It will now be clear how both induction and deduction enter as methods in physical science. The general law is established by means of the analytic method of induction; it is a process of abstraction and generalization, based on the nature of things. Having obtained the general law, *the law is then applied to all further cases* by the synthetic method of deduction: the water in the street and the lake in the park will also freeze, if the temperature drops to $+32^{\circ}$ F.; the diamond in this man's ring and in this lady's brooch will also burn, if exposed to sufficient heat. Both induction and deduction are necessary for truth: induction for its *discovery*, and deduction for its *proof*. The mind first argues from the effect to the cause, and then from the cause to the effect.

D. Card. Mercier gives us a concise but effective illustration of scientific method in its various stages. "Let a chemist take some *hydrogen*, a gas without color, taste, or smell; which burns with an intensely hot bluish flame; which is 14.4 times lighter than air, 22.326 litres weighing 2 grammes. Let him take another and very *different* sort of gas, chlorine; of a yellowish color and an unpleasant, suffocating smell; density 2.44, weighing 35.5 times more than hydrogen, 22.326 litres weighing 71 grammes.

"Let the chemist mix those two gases in a glass vessel, and place it in the sunlight: a violent combination will suddenly take place, disengaging 22 thermal units or calories of heat; after which the chemist finds in the vessel a new body, whose distinctive properties have acquired for

it the name of *hydrochloric acid*. This new body will attack most of the metals and combine with them to form various salts; it will combine with the aqueous vapor of the atmosphere to form a colorless, acid solution, etc.

“So far he has *observed a fact* [first step]. Next, how is it to be explained? Why did it happen? What is its cause? He *supposes* that it is due to some *law* of nature [second step]; he supposes the formation of hydrochloric acid to be due to some *property* inherent in those two gases, acting in certain conditions, still to be determined. This suspicion of his is an *hypothesis*, which he must now proceed to verify.

“For this latter purpose [third step] he will multiply and vary his experiments. For example, he will let the sunshine act on a mixture of chlorine and oxygen; supposing a priori that they too will combine; but he finds that they will not. It is not every two gases, therefore, that will combine under the action of sunlight. But, perhaps, at least any quantities whatever of hydrogen and chlorine will combine? A priori, again, the supposition is permissible; but again it is negatived by the facts. For repeated experiments establish that they will combine only in the proportion of 1 to 35.5 by weight, or — which is the same — of 1 to 1 by volume. When those proportions are brought together under the influence of sunlight — no matter how little or great the absolute quantities may be, milligrammes, centigrammes, decigrammes — the combination will take place. On the other hand, when those proportions are not maintained, the quantity of the one which is the excess of its due proportion to the total quantity of the other, will remain over, unaffected by the combination.

“Here, then, are other facts in presence of which the observer finds himself: Two definite gases, mixed in definite proportions of 1 to 1 by volume of 1 to 35.5 by weight, combine under the action of sunlight — the absolute quantities of each being indifferent to the result and indefinitely variable. Neither of these gases, mixed with any other gases, combine with the latter in the same conditions and proportions; if mixed with each other in any other proportions than those indicated, they will not combine completely, but will leave the surplus above the proportion unmolested. Further, the chemist remarks that, after the combination, one volume of hydrogen and *one* volume of chlorine, combining under definite conditions of temperature and pressure, yield *two* volumes of hydrochloric acid gas.

“Are all those facts — which recur repeatedly in similar circumstances — the result of mere chance coincidences of disconnected and indifferent causes? They are not: they cannot be. Reason will not admit that any such complex, harmonious, stable series of facts could be due to chance. They must be the expression of a law; they must find their sufficient reason in the nature of the combining bodies.

“The chemist finds this sufficient reason in what he calls the ‘affinities’ of the reacting bodies; the metaphysician, in ‘*properties* inherent in the *nature*’ of those bodies, and indicative of the energies of those natures. The language is different, but at bottom the idea is the same: *There are in the world such complex, harmonious, stable series of facts as cannot be due to chance activities, but must be the result and expression of natural laws*; and the formation of

hydrochloric acid from hydrogen and chlorine is a manifestation of such a law.

“Thus it is that, from the total complex group of circumstances in which he has witnessed the formation of hydrochloric acid, the chemist abstracts or gathers by induction the truth that hydrogen and chlorine have the *property* of combining in the proportions indicated, with a disengagement of 22 calories of heat for the formation of each molecule-gramme of hydrochloric acid. The combination being, moreover, found to be independent of the particular place and time, and of the absolute quantities of the bodies used, he can foretell with certainty that *always* and *everywhere* those gases will combine in those definite proportions to form the compound body, when submitted to the action of sunlight under the same general conditions.

“In a word, the *law* of hydrogen and chlorine is to combine, *always* and *everywhere*, under the above mentioned conditions. The chemist who has observed all the facts and extracted that law from them has made an induction.”¹

In this brief but lucid instance of induction we can observe all the steps usually taken in this scientific method. We have (1) the *observation* of the facts in the case; (2) the *hypothesis* as to the probable cause of the phenomenon; (3) the *proof* or verification of the hypothesis; (4) the *explanation* of the *law*; (5) the *application* of the law to all similar instances. The last step (6) is the final verification of the law in question and is a process of *deductive* reasoning, because from this point on the mind argues from the

general law to all further specific cases and individual experiments. We see, therefore, that deduction must always climax the inductive method, if induction is to be of value to science because only in this way will the experiment cease to be an isolated case and become a generalized principle of *necessary and universal application*. In this deductive syllogism, the law becomes the major premise of the First Figure, and the single instance under consideration becomes the minor premise. The syllogism can be formulated as follows:

Hydrogen and chlorine, mixed in the proportions of 1 to 1 by volume, will yield two volumes of hydrochloric acid, liberating 22 calories of heat for each molecule-gramme of hydrochloric acid, under the influence of sunlight.

Here in this receptacle hydrogen and chlorine are mixed in the proportion of 1 to 1 by volume and are exposed to sunlight.

Ergo, here in this receptacle these gases will yield two volumes of hydrochloric acid, liberating 22 calories of heat for each molecule-gramme of hydrochloric acid.

We notice further that the discovery of the general law here is not the result of anything like a *complete enumeration* of all possible quantities of hydrogen and chlorine in all possible combinations and circumstances. Scientists do not and could not attempt such a process. If such a complete enumeration were necessary, no general law could ever be enunciated by science because it is impossible to make such a complete enumerative induction. The general law is the result of an abstraction based on *cause and effect*, the nature of the things being the cause

and the *phenomena* observed being the effect. Observations and experiments are made in such number and under such varying conditions until the mind clearly perceives that the results obtained are the direct effects of the respective *natures* of hydrogen and chlorine. Once this is established, there is no need of multiplying the experiments; since the nature of hydrogen and chlorine remain the same in all conditions of time and place they will produce the same phenomena *always* and *everywhere*. This being certain, the general fact is expressed in a general *law*, and this law can now be applied without fail to every individual instance which may arise in the world or in the laboratory. Science has been increased by a new law, and the mind has been enriched by a new truth.

The relation of the inductive *law* to the individual *phenomena* is the same as the relation of the universal *idea* to the individual *things*. Both are the result of the abstractive power of the mind, leaving aside the individuating differences and grasping the essential *nature* common to them all. Thereby the idea and the law become *abstract, necessary, and universal*, applicable to the whole class and to every member of the class, irrespective of time and place. It is precisely this necessary and universal character of the idea and the law which makes them valuable for science and philosophy and constitutes a distinct advance of human knowledge. If the law agrees with the facts, it is true; otherwise it is false. Scientific laws are expressed in definite categorical statements; and truth, as we know, is only found in categorical judgments which are an actual representation of facts as they exist

independent of the mind. The laws of science, therefore, like the universal ideas, are not mere figments of the thinking mind, but representations of reality.

Such is the nature of induction. The instance given above of the combination of hydrogen and chlorine is merely an illustration of the method of induction as used in every department of physical science. The details will vary, of course, according to the individual problems to be solved, but the fundamental principle of procedure is the same: it is an abstraction, passing from the particular to the universal, from the effect to the cause, from the logical part to the logical whole, from the phenomena to the law.

SUMMARY OF CHAPTER XVII

A mere comparison of ideas will not always enable the mind to express their identity or non-identity.

1. Some simple facts can be known by immediate observation; axiomatic truths can be known by an analysis of ideas. But the great bulk of *scientific* truths demand a process of reasoning to establish their truth. Hence, the necessity of understanding the laws of consistency in the various forms of argumentation.

Formal truth (consistent arrangement) and *material* truth (statements of facts) are necessary in an argument, in order to be certain of a true and consistent conclusion. The material truth of premises can only be discovered by a *study of nature*, and this demands a knowledge of the proper *scientific method*.

2. *Method* is the *proper arrangement of our mental processes in the discovery and proof of truth*. The synthetic method proceeds from the universal to the particular, from the cause to the effect, from the logical whole to the logical part, from the law to the phenomena. This is *deduction*. The *analytic* method proceeds in the reverse order. This is induction or the experimental method of the physical sciences.

3. *Induction is the legitimate inference of universal laws from individual cases*. It is a process of abstraction, based on an understanding of the nature of the reality under observation, on a perception of the relation of *cause and effect*, the nature being the cause and the phenomena

being the effect. Hence, scientific laws are not the result of a complete enumeration of instances.

Chapter 18

THE LOGICAL FOUNDATION OF INDUCTION

INDUCTION IS THE GENERAL METHOD EMPLOYED BY THE PHYSICAL sciences to ascend from the concrete, isolated, individual occurrences of nature to the generalized, universal, necessary laws which govern these phenomena. Due to induction as a method of discovering scientific truths, the experimental sciences during the last two centuries have made tremendous strides in the advancement of knowledge. The importance of induction can, therefore, hardly be overrated. Its very success proves that certain very definite *laws of thought* underlie its operations, giving it logical validity. What, then, are the logical *foundations or grounds or reasons* upon which the validity of induction is based? This is a vital question, because the answer will be the philosophic vindication of induction. And the answer is, that induction is grounded on two fundamental principles: the *Principle of Causality and the Uniformity of Nature*.

THE PRINCIPLE OF CAUSALITY

The Principle of Causality is an outgrowth of the *Principle of Sufficient Reason*, just as the latter is a development of the

Principle of Identity and of the Principle of Contradiction. These principles cannot be proved and they need not be proved; they are *self-evident* and need only be explained, in order to show their truth and validity.

In virtue of the Principle of Identity 'A thing is what it is.' Nothing can be simpler and truer. This is common sense and good philosophy. Then, in virtue of the Principle of Contradiction, 'A thing is what it is, and *it can be no other*'; if it could be another, it would not 'be what it is.' In consequence of this, the Principle of Sufficient Reason is equally self-evident: 'Everything must have a *sufficient reason* to be what it is.' If it had no sufficient reason for its existence and being, it would have no existence and it would be nothing. If a thing could exist without sufficient reason, it would exist (that is the supposition) and not exist at the same time (because it has no *sufficient* reason for its existence), and that would be in violation of the Principle of Contradiction. Therefore, if a being exists, it must have a sufficient reason *why it exists* and why it is *this particular being* rather than another.

Now, the sufficient reason for the existence and being of a thing must lie either in the *thing itself* or in some *other thing*. There is no other alternative. If a thing has the sufficient reason for its existence and being in itself, then it is *self-sufficient and un-produced*. The reason is plain. The very fact that the sufficient reason for its existence and being is said to lie in *itself* presupposes that its existence and being is not due to an other. But in that case its existence and being could never be produced. If it were ever non-existent, and the reason for its passage from non-

existence to existence would lie *in itself*, then, it would obviously have to bring itself from non-existence to existence; in other words, it would have to produce itself; it would have to make itself from *nothing into something*. But to *produce and make something is to act*, and to produce and make its own existence (while it is still non-existent) and its own being (while it is still nothing), is to act before it can act and to exist before it exists and to be something before it is a being; and that, of course, is a contradiction and therefore impossible. Hence, if a thing has the sufficient reason for its existence and being *in itself*, it must of necessity be un-produced and eternal. Such a being is God.

On the other hand, then, if a thing has the sufficient reason for its existence not in itself, but *in an other thing*, it must for that very reason be produced. This means that, whatever it has in its existence and in its being, it has because it is *produced by some other being*. Here we have the idea and *Principle of Causality*. The thing that *receives* its existence and being from some other thing is the *effect*, and the thing that *produces* the existence and being of some other thing is the *cause*. The Principle of Causality, therefore, is the outgrowth of the Principle of Sufficient Reason, and it can be stated: 'Whatever happens (occurs, changes, begins to be) has a cause'; or, 'Whatever is *contingent* (i.e., is not the self-sufficient reason of its own existence and being) has a cause for its existence and being,' or, simply, 'Every effect has a cause.' A being that is self-sufficient is also self-existent and uncaused and necessary. Reversely, then, whatever has not the sufficient

reason for its existence and being in itself, demands with *intrinsic necessity* that some other thing be the cause of its existence, to bring it about and make it happen and to give it *everything that it is*. The Principle of Causality, therefore, is a *necessary principle* for all contingent and temporal beings which undergo change, and it is precisely in this connection that the Principle of Causality forms the logical foundation of induction.

All the physical phenomena of the universe around us, starting from the atoms and ending with the stars, are in a continual state of change; they are, consequently, not necessary in their being, but contingent. It is the purpose of science to discover and prove the causes which produce these phenomena and express them in general *laws*. It will, therefore, be necessary to have a clear conception of the nature and *kinds* of causes which are active in the production of a thing.

From the above it will be apparent that a cause is the sufficient reason for the existence and being of a thing which has not this sufficient reason in itself. A *cause*, then, can be defined as *anything that contributes in some positive manner toward the production of another thing in its existence and being*. The traditional teaching, begun by Aristotle, continued by the medieval Schoolmen, and reaching into our own age, enumerates four causes: two are extrinsic to the produced thing, the *efficient* and *final* causes; and two intrinsic to the produced thing, constituting its inner nature, the *material* and *formal* causes. Although the deeper examination of the doctrine of causes belongs to the department of philosophy called

ontology or metaphysics, a brief exposition of the nature of causality and of causes will not be out of place in this connection.

Since a cause contributes in some positive manner toward the production of a new thing, it really makes this thing *to be what it is*. The *efficient* cause does this, because it is the *agent which actively produces* the thing or a new state of the thing. The *final* cause does it, because it is the *purpose or aim* which induces the efficient cause to act and directs this action throughout its operation. The material cause does it, because it is that *inner, passive part* of the produced being which is determined and changed by the action of the efficient cause. And the *formal* cause does it, because it is the *inner, active part* of the produced thing which is the determining element of the new (caused) reality in the produced thing. Examples will make these ideas clearer.

A sculptor desires to produce a statue of, let us say, George Washington. His *purpose or aim* will obviously influence the being of the statue. Shall it be a monumental piece of work for a public place or building? for a hall in a private home? as an ornament for a mantelpiece? Whatever he decides, the purpose and aim he has in view will positively influence the production of the statue from beginning to end; it is the *final* cause. The sculptor next selects his medium, for instance, marble. This he chisels and *carves*, until the figure he has in his mind is a finished product; his *active* work is the *efficient* cause of the statue. But the *marble* itself contributes a positive influence in the making of the statue. The statue would be entirely different,

if it were made of wood or clay or porcelain or bronze or granite. But the marble is only the passive, determinable medium which has to be shaped; it is, therefore, the *material* cause of the statue. Finally, the *figure* or shape of the statue, in as much as it represents George Washington, makes the statue really to be a statue, distinguishing it, for instance, from a painting or photograph of the man. Its influence, too, is positive, because it actually determines the indifferent medium of marble to be just this kind of statue rather than another; it is the *formal* cause of the statue of Washington as Washington.

Another example. When hydrogen and oxygen unite to form water, the *energies* of both substances reacting together are the *efficient* cause of the new substance, water. The masses of hydrogen and oxygen, which pass from these substances into the new compound, are the *material* cause of water. That internal principle which gives to these masses the new properties characteristic of water is the *formal* cause of water, because it constitutes water as such and distinguishes it from other physical substances. The *new compound*, water, is the *final* cause, because it is the *intended result* of this chemical action, as can be seen by the fact that hydrogen and oxygen, due to their chemical affinity, have the *innate tendency* to produce just *this* specific thing and not another.

These four kinds of causes, each in its own characteristic way, are positive factors in the production of a thing. In physical nature, of course, this 'production' is only a 'change from one kind of thing to another kind of thing,' and it presupposes the existence of a thing before it can be

so changed. Absolute production of a being from non-existence to existence would be creation, the highest type of causation; but we do not observe this kind of causation in nature. Whatever changes take place in nature occur among already existing beings, and the effectiveness of their causality is thereby limited to producing '*one kind* of thing from *another kind* of thing.' The natural sciences, of course, consider merely this type of cause, because that is the only type encountered in physical phenomena. For the same reason physicists, ordinarily speaking, are not interested in the problems of *free will* as a cause, because the province of nature which they study consists of beings that act according to the non-free forces dominating the universe and its phenomena. Hence their continuous reference to 'necessary causes in the course of their research work. This is a somewhat one-sided attitude, because man with his free will is as much a part of physical nature as the material bodies with their non-free energies of heat, light, electricity, motion, and other causal agencies. However, as long as these scientists restrict their investigations to material beings and refrain from passing judgment on problems outside their proper domain, the philosopher need not quarrel with them.

Scientists, then, consider merely the *non-free material causes* at work in the universe. Many of them, however, confuse *cause* and *condition*. There is a great difference between the two. A cause, as we have seen, is something which 'positively contributes toward the production of a thing in its existence and being.' A *condition*, on the other hand, is something *which enables the cause to produce an*

effect, without actually contributing toward the production itself. A few examples will illustrate the difference. The winding of a clock is a condition necessary for its running, but it does not actually make the mechanism go; it is the mechanism itself which does the work. Pressing the button of an electric bell is a condition for its ringing, but that merely closes an electric circuit; it is the current which operates the bell. Throwing a switch will flood the room with light, but this is only a condition, since it is the electricity heating the filament of the lamp which causes the filament to glow. Opening a bridge may be a necessary condition enabling a boat to pass through; but it will not make the boat move. Unlocking a prison door is a condition for a captive to escape, but it does not actually bring him into the open. Pressing the foot on the accelerator may be required to feed more gasoline into the cylinders of the motor; but this does not explode the gasoline, which is the motive power of the engine to drive the car with greater speed. Pulling the trigger of a gun is a necessary condition to explode the charge in the cartridge and thereby expel the bullet; but it is the expanding force of the ignited powder which is the actual cause of the speeding bullet.

This last instance, however, exhibits a peculiar characteristic. Pulling the trigger has a direct influence on *releasing* the energies necessary to producing the effect, on *originating* a chain of activities which finally bring about the agency of the cause in producing its result: the pressing of the trigger releases a spring which drives the firing pin with great force against the percussion cap, so that the percussion cap ignites the charge in the cartridge, making

the charge explode. Such an active, *originative condition* is often styled a *determining cause*, and it plays an important part in science. It was known, for instance, that a certain germ was the cause of sleeping sickness, but its originative condition or 'determining cause' was unknown, until it was discovered that the bite of the tsetse fly introduced the microbe into the system of the unfortunate victims. Similarly, pollination is the real cause of the fertilization of most types of plants, but the actual fertilization of widely separated plants was in many cases a mystery, until it was realized that certain insects were the carriers of pollen from flower to flower.

Some scientists deny *the existence of causes* entirely, and admit only *conditions* with inevitable results or *antecedents* with invariable consequents. One might consider this merely a matter of words and names, were it not for the fact that a distinct *theory of knowledge* has introduced this radical difference of viewpoint concerning the reality of causes.

It is the *Empirical School* of thought, originated by John Locke (1632—1704) and developed by David Hume (1711—1776) and John Stuart Mill (1806—1873), which reduced all knowledge to experience and sense perception, thereby practically identifying mind with matter and intellectual knowledge with the simple apprehension of phenomena, without any possibility of reasoning beyond the material facts of the occurrences in nature as they appear directly to our senses. According to this sensist theory, then, all we can perceive is a mere succession or sequence of changes, and 'a cause' is nothing but the total sum of all the positive and

negative conditions taken together (as an antecedent), so that, when these conditions are realized, the phenomenon (as a consequent) invariably follows. Of course, if we grant this theory of knowledge as true, then our entire knowledge of causation in nature can be but an 'invariable sequence' of events as they follow each other. Tuberculosis, for instance, would then be explained as follows: a germ lodges in the lung; there follows a multiplication of bacilli; lung tissue is dissolved; holes appear in the lung; a profuse hemorrhage follows; the person dies. But I cannot say that the original germ *produced* the following germs; and these germs *produced* a dissolution of tissue; and this destruction of tissue *produced* holes; and the action of the germs *produced* a lesion in the pulmonary arteries; and this lesion produced a profuse hemorrhage, which in turn *produced* death. To argue in this fashion would mean to conclude from effect to cause; but that is not permissible, because we cannot go beyond what our *senses perceive*, and our senses perceive only the *sequence of phenomena* as they follow one after the other; we perceive merely changes succeeding previous changes and nothing more: there are only 'conditions,' not 'causes,' and 'sequences,' not 'causality.'

This confusion of 'cause' and 'condition' is not the result of any particularly acute observation of the phenomena of nature, but the offshoot of a *theory of knowledge*; it stands and falls with this theory. While criteriology and psychology, and not logic, are the proper departments of philosophy which must disprove Empiricism as a theory, it will suffice here to point out that *our own experience* is witness to the

fact that we are conscious of causality in the meaning of actually *producing* effects. No amount of theorizing can remove the conscious and evident experience that we, with a perceptible expenditure of energy, propel ourselves forward and produce motion in our body when we walk or run or swim or skate or do similar things; and the difference between our own causality and the causality of other things is observed with particular keenness, when we unwittingly tumble down an embankment, or, are thrust violently aside by some other person, or are thrown headlong out of an automobile which was caught in a collision. We *feel* with pain that there is no mere sequence of phenomena here, but an actual producing of very definite impressions: these are causes and effects, not conditions and consequents.

These experiences from our daily life could be multiplied by the thousands. The consciousness of effort in producing tangible results, whether on the part of unskilled labor in digging ditches or on the part of highly trained mechanics in fashioning and operating machines or even on the part of the specializing scientists in making experiments, is an irrefutable witness of all mankind to the fact that human bodies can and do experience the workings of causality in their actions. If the theory of materialism and empiricism cannot explain these facts, then such theories must be discarded as unscientific and un-philosophic and illogical. The facts are there and cannot be disputed away by any *a priori* theory of knowledge. And just as we are conscious of the causality of our own body when our arm wields an ax and splits a log, so we must also attribute the same sort of

causality to the flash of lightning which rives the trunk of a tree to splinters; for if our own bodies can actually produce effects, we must ascribe a similar causality to other bodies, since they produce the same kind of effects. The much vaunted principle and method of *induction* forces us to the scientific conclusion that all bodies, whether living or inanimate, are causes in the strict sense of the word as 'things which contribute in some positive manner toward the production of another thing in its existence and being.' At bottom, scientists are always looking for the *causes* which will account for the production of definite phenomena, even when they speak only of 'conditions' and 'antecedents' and 'consequents' and 'invariable sequences.' Scientists, of course, who are not adherents of an empiricist and sensist philosophy, are unanimous in the admission that it is the function of scientific induction to discover and prove the *relation of causality* in the phenomena of nature. The Principle of Causality, then, is a part of the *logical foundation of the inductive method*. Without this principle induction is futile and must remain sterile of knowledge and truth.

THE UNIFORMITY OF NATURE

Taken alone and by itself, though, the Principle of Causality, as the logical basis of induction as a scientific method, is insufficient to justify the broad scope it has and the far-reaching claims it makes with regard to the discovery of truth and the advancement of permanent knowledge. The Principle of Causality merely demands that every physical

change and every natural phenomena must have a cause or sufficient reason for its presence. It accounts, therefore, only for those occurrences in nature which *actually happen*. It explains only the *individual, isolated happenings*, stating that, since these are physical effects, they must have a physical cause. But of itself the Principle of Causality will not justify the establishment of *universal laws* by scientists, because such laws are generalizations which go *beyond* the *individual* cases which have been observed. The Principle of Causality will apply to each *single* phenomenon that occurs, and that is all.

Like this: Fire destroyed a building; something caused this fire. A boiler exploded; something caused this explosion. A man died; something caused his death. An epidemic of dysentery developed at the Century of Progress Exposition in Chicago; something caused this disease. An earthquake shook San Francisco; something caused this upheaval. The sun was darkened in broad daylight; something caused this eclipse. Floods swept the country; something caused this sudden deluge. A cyclone destroyed a city; something caused this tremendous rush of air. Northlights appeared in the sky; something caused this vivid display. An oyster developed a pearl; something caused this curious growth. The mercury fell in the barometer; something caused this drop of the column. And so on, with the million and one things that occur day after day. Each single event, due to the Principle of Causality, demands some physical agency as the sufficient reason for its presence, because it is an *effect* which requires a cause as its adequate explanation.

But scientists go much further in their search for knowledge.

From a number of such instances, similar in cause and effect, they establish *general laws of universal validity for all times and for all places and under all circumstances*. At least, such is their claim for these laws. These laws of nature are supposed to have operated in the same way during the ages of the past throughout the universe; they are supposed to be valid in the same way at present; and they are supposed to remain with the same necessity of operation for all the eons of the future. For they are, according to the assumption of the scientists, *universal and necessary laws* which control all physical agencies and their phenomena. The laws of light, heat, electricity, motion, chemical affinities, and all other forces of nature, have always, and will always operate in the same manner, independent of time, place, and circumstance. It is only on the basis of this *postulate* of science that scientists can reason about physical phenomena and their development in the past and predict similar events in the future.

Now, it is obvious that scientists cannot arrive at a knowledge of such *universal* laws by means of a *complete enumeration* of all the instances in which a certain phenomenon occurred. For instance, it is impossible for scientists to investigate every single case of a falling body, in order to establish the law of falling bodies. It is impossible for them to examine all cases of the effects of gravity, so as to enable them to establish the law that all bodies throughout the universe are affected by the forces of gravitation according to the product of their masses and

inversely as the square of their distances from each other. They could not follow up every drop of water in the oceans to see whether the ebb and flow of the tides were really due to the gravitational pull of the moon. Neither could they investigate every drop of water in order to prove the law that it is composed of hydrogen and oxygen in the proportion of two to one in every case. Nor could they examine any other law of chemistry, physics, astronomy, biology, and the other sciences this way, so as to arrive at the knowledge of such laws by means of *induction* on the basis of a *complete enumeration*. The number of actual phenomena observed and studied, compared to the innumerable instances throughout the world, even in our present day, is so insignificant and ridiculously small, that no general law could ever be formulated from them, if this law had its sole foundation in the *enumeration* made in an inductive process. Nevertheless, scientists do, notwithstanding the incompleteness of their enumerative survey, claim a *necessary and universal validity* for the laws of nature which they formulate. On what logical grounds? If the necessity and universality of these laws is nothing but a purely arbitrary assumption on the part of scientists, then induction, as a logical method of scientific knowledge, might as well be cast into the dustbin of useless and discarded theories.

It must be apparent, then, that the inductive method as such and the Principle of Causality alone will not be able to give universal validity to the general laws established by scientists. Another fundamental principle is needed for that, and it is the principle of the *Uniformity of Nature*. Put into a

categorical statement, the principle of the Uniformity of Nature reads:

Nature is uniform in its causality; or, to give it a different phrasing: The same non-free causes, under the same conditions, will always produce the same results. There can be no doubt that no induction could be validly made from particular occurrences to general laws of universal value, unless nature is uniform in its causality; because, if the action of nature would not be uniform and regular and ordered, we could never be sure that what happened today also happened yesterday and will again happen tomorrow. The uniformity of nature must assuredly be *presupposed*, if these general laws are to stand. The uniformity of nature is, therefore, a necessary *postulate and assumption* for all induction.

But what right have scientists (or anyone else, for that matter) to assume that nature acts *uniformly* in the past, present, and future, on the earth, on the sun, and everywhere in the universe? True, our limited experience of phenomena shows uniformity. Every time we dissolve water we obtain hydrogen and oxygen in the proportion of two to one, and when we reunite these elements we obtain water. At sea level, whenever the temperature drops to +32° F., water freezes. Gold and platinum, insoluble in any of the common acids, are always dissolved in *aqua regia* (a mixture of one part of nitric acid and three parts of hydrochloric acid), being converted into chlorides. As often as the 'guinea and feather' experiment is made in a vacuum tube, they reach the bottom of the tube simultaneously, thus illustrating the law of falling bodies. Light, whenever and

wherever measured, always shows the same velocity. And so forth. These and similar experiences certainly suggest to our minds the principle of the Uniformity of Nature; they are the *proximate reason* why we feel justified in assuming that nature is arranged in orderly fashion and governed by uniform laws of universal application.

But this extremely limited experience of ours will hardly justify the sweeping generalization embodied in the Uniformity of Nature, embracing, as it does, the entire universe in all its immensity of time and space. Certainly, the *sensist* and *empiricist*, who acknowledges sense perception as the *only* legitimate means of knowledge and science, has no right whatever to leap from the infinitesimal data of our experience into the limitless space of the world and into the dark of the past and the future; according to his own avowed principles he cannot reach out beyond the immediate sphere of experience, and so for him the Uniformity of Nature must be an unwarranted assumption if he wishes to be consistent. The sensist and empiricist can, therefore, find no logical foundation for induction; and the general laws of science, which are the result of induction, must evaporate into thin air.

Unless, then, we can find a *logical foundation* for assuming that nature is uniform in its operations under all conditions, we have no right to assert that there are such things as *universal and necessary laws* of nature; and in that case science must collapse, like a house built on shifting sand. The whole problem of the Uniformity of Nature simmers down to this: Why must nature be uniform in its causality? Because the beings which constitute nature

are causes which operate with *necessity* and, therefore, must always operate in the same way, i.e., uniformly. But why must they operate of necessity? Because their causality is *determined* by their very *essence*, and their essence is always the same. But why is their essence determined so definitely that it must always be the same and cannot change? Here is the crux of the whole question, and there is only one possible answer: Because they were created, and the Creator, in giving them their essence, endowed them with certain *definite powers and tendencies* which they, being non-free agencies, necessarily strive to realize. In consequence of this, their causality is always uniform. All the chemical elements and all their compounds will retain the same essence and the same activities, insuring a Uniformity of Nature; because the Divine Intelligence has made the world not a hodgepodge of unrelated and unstable essences, whose activities change in their causality from hour to hour, but a magnificent 'universe,' an ordered and harmonious whole, which moves according to *uniform laws* impressed upon it by His Omnipotence and Wisdom.

Here, then, we have a logical and adequate explanation for the Uniformity of Nature, the only one which will solve the problem. In the light of this view, a number of things become apparent. It explains the orderly arrangement of the world, rising in a graduated scale from the infra-atomic construction of the elements and the biological similarity of living structures up to the stupendous co-ordination of planetary systems and star galaxies in the vast expanse of the heavens. It explains why the universe is built up of the same elements and the same forces and regulated by the

same fundamental laws, controlling everything from the core of the proton out to the uttermost fringe of creation. It explains the inherent rationality of nature, since its laws can be expressed in mathematical formulae whose precise and complicated calculations tax the intelligence of man to the highest degree. It explains the beauty in the world (so seemingly useless) as seen in the delicate filigree work of a diatom, in the tender heart of a budding rose, in the gaudy splendor of a butterfly's wings, in the brilliance of a peacock's iridescent tail, in the gorgeous effulgence of the aurora borealis, and in the awe-inspiring magnificence of the perennial stars. It explains, too, the evident *destiny* which guides all things toward the realization of their being, according to a definite, world-embracing plan, arising out of the mists of the past, carried through the present, and going toward its gradual fulfillment in the unknown ages of the future.

It is this *evident destiny* of the world, manifesting itself in every phase of nature, working according to some deeply harmonious design, *unceasingly, constantly, uniformly*, which is the only guarantee that the world will continue for an indefinite period in the future, provided the Creator Himself does not interfere and stop it in the middle of its course. This, of course, He could do at any time, just as He could change the essences of all things in the twinkling of an eye. There are, however, no reasons or indications to suppose this, as far as we can see. Nature was uniform in its causality in the past, is so at present, and will remain that way in the future, simply because it is the intelligent

handiwork of the Creator. His Wisdom and Providence are the reasons for the Uniformity of Nature.

Returning to the starting point of our discussion, we now understand the *ultimate logical foundations of induction* as a scientific method for the discovery of truth. Two principles are necessary to make induction a valid method: the *Principle of Causality* and the *Uniformity of Nature*. Science bases its universal laws, not on a complete enumerative induction of all possible phenomena, but on the *causality* inherent in the nature or essence of things; this enables it to rise from the particular to the universal and from the contingent to the necessary, even though its induction rests on an incomplete enumeration. This relation of causality is then expressed in *laws* which have a necessary and universal application to all phenomena which fall under these laws, whether in the past or present or future, due to the *Uniformity of Nature*. And this *postulate* or assumption of the Uniformity of Nature has its justification in the fact that the universe is the handiwork of the Supreme Intelligence, who has fashioned it according to a definite plan and has given it a determined destiny which, barring His own voluntary interference, must continue in the future to realize His providential designs.

In this double principle, therefore, as just explained, we have the philosophic vindication of induction as a true scientific method for the discovery of truth and the advancement of human knowledge, in as far as it pertains to the physical world.

SUMMARY OF CHAPTER XVIII

The *logical foundations* or grounds, upon which the validity of induction as a true scientific method are based, are the Principle of Causality and the Uniformity of Nature.

1. *The Principle of Identity* gives rise to the Principle of Contradiction, and this in turn gives rise to the *Principle of Sufficient Reason*: 'Everything must have a *sufficient reason* to be what it is in its existence and being.' If a being has this sufficient reason in *itself*, it must be self-sufficient and un-produced in its existence and being; but if its sufficient reason lies in *another*, it is produced by some other being, and this latter is then the cause of the former, and the former is an *effect* of the latter. The Principle of Sufficient Reason, therefore, leads logically to the Principle of Causality: 'Whatever happens (occurs, begins to be, changes) has a cause for its existence and being.'

A *cause* is anything that contributes in some *positive* manner toward the *production* of another thing in its existence and being. There are four kinds of causes: ***efficient, final, material, and formal***. A condition is something which enables a cause to produce an effect, without actually contributing toward the production itself. Empiricists deny the existence of causes and effects and admit only 'conditions' and 'antecedents' as causes and 'consequents' as effects, while causality is to them only an 'invariable sequence.'

Science, then, basing its general laws on the Principle of Causality, has in this principle a logical foundation for its

inductive method.

2. The *Principle of Causality* alone, however, would be insufficient for the validity of *universal and necessary laws*, because it merely demands that every individual effect must have an adequate cause. The *Uniformity of Nature* is a necessary *postulate* of science, in order to explain the universality and necessity of these laws, since they are supposed to be valid for all times and places and in all circumstances. The Uniformity of Nature as a principle of scientific induction is not the result of a *complete enumeration* of individual cases, because no such enumeration is possible. The principle of the Uniformity of Nature can only be assumed and logically accounted for on the basis that an Intelligent Creator has made the universe into an *orderly, uniformly acting whole*. This alone will explain the Uniformity of Nature.

Science, then, in the Principle of Causality and in the Uniformity of Nature has a logical foundation for induction as a scientific method for the discovery of truth.

Chapter 19

INDUCTIVE METHOD

UNLIKE PALLAS ATHENA ISSUING FROM THE BRAIN OF ZEUS, scientific knowledge does not spring from the genius of man in the fullness of its being. Usually it originates in some germ-idea, develops slowly through a protracted period of growth, and gradually matures, until it is born in labor and pain. Nothing comes to man except as the result of great patience and laborious effort. Scientific achievement is as a rule the climax of accumulated work, painstaking study, concentrated attention to detail, unflagging pursuit of the elusive causes of nature, a critical mind unbiased by any pet theories, and a passionate love of truth. For this is the scientific temper, the indomitable spirit of which will survive a thousand defeats and forge its way to ultimate success.

It is the purpose of all science to discover the *causes* of the phenomena of nature and the laws according to which these causes operate: true knowledge is the knowledge of causes. But this is a most difficult thing to attain, because cause and effect do not appear in an isolated form. Nature is most complex in its operations, and a myriad forces are continually at work together, interwoven and interrelated in the most diverse fashion, producing phenomena of

kaleidoscopic variations through the interplay of many causes and effects. A storm in the springtime, with its changes of temperature, its wind velocities, its lighter and denser clouds, its sleet and rain, its thunder and lightning, presents a group of phenomena in which the relation of cause and effect is very obscure to the unscientific mind. Even as recently as two hundred years ago the exact nature of lightning was unknown to science, while today its cause is a commonplace of knowledge to the child in the elementary grades. There are a hundred problems in the appearance of a storm for which science must seek the solution. And this is only a single instance. Nature is replete with mysteries, from the fractioning of a radium atom to the star-building formation of cosmic nebulae millions of light-years away.

How does the mind attempt to solve these riddles of the universe? By *induction*. Induction is the key to the laws of nature, and observation is the chief factor in induction.

OBSERVATION

Observation consists in the close scrutiny and examination of natural occurrences. The marshaling of all the facts in their proper order and the analysis of these facts with a view to discovering the *causal connections* between certain 'antecedents' and 'consequents' which appear in 'invariable sequences' is the function of the intellect. Not all 'invariable sequences' show immediate causal relations. Night follows day and day follows night in an 'invariable sequence'; but the one is not the cause of the appearance of the other. The

seasons follow each other in an infallible rotation; but the 'antecedent' here does not *produce* the 'consequent.' A clear atmosphere at night is always followed by a greater brilliance of the stars; but the stars are not *made* to shine brighter, nor do they *actually* burn with a *greater* brilliance, because of the clearer air around the earth. Now, it is the intellect alone which can distinguish between mere 'sequence' and 'causality' in the physical connection of events. The senses, which are the instruments of observation, are only capable of noting the 'sequence'; it is the intellect which must discern the 'cause.' The intellect, therefore, relies on the accuracy of the senses to furnish it with the necessary data, in order to enable it to draw its conclusions regarding phenomena which the senses register.

The senses, marvelous though they are, have their limitations; their range of perception is fixed by definite boundary lines. Ultra-violet and infra-red light waves are imperceptible to the eye; excessive smallness or largeness of objects are impassable barriers for vision; great distances, too, hinder its effectiveness. This applies with even greater truth to the other senses. All these factors play an important part in the proper observation of nature and impede the intellect in its search for facts. Little wonder, then, that man could make but slight progress in some of the sciences until the invention of the telescope and the microscope. These two appliances alone have widened the field of vision for man to an amazing degree, enabling him to reach out into the vast distances of the interstellar regions and down into the depths of the sub-visible

universe. Many phenomena now ceased to be mysteries. Equipped with the increased vision of these mechanical eyes, man's intellect found a new world of facts for observation and penetrated into the hidden recesses of nature.

Nature has been forced to yield many of her secrets through the mere instrumentality of the telescope and the microscope. Galileo, in 1610, observed the light-phases of Venus through his primitive instrument and thereby gave valuable evidence for the truth of the Copernican theory of the heliocentric planetary system. Then Herschel, in 1781, with his improved seven-foot Newtonian telescope, made the sensational discovery of the planet Uranus. And with these successes and the subsequent improvement of the telescope there began a new era for the science of astronomy. Since the day when the astonished eyes of Antony van Leeuwenhoek (1632—1723) peered through his self-made microscope and observed for the first time in human history the protozoa that swarm in a drop of water, the march of progress for science in this direction was hardly less phenomenal than that of astronomy. An immense array of scientific facts has accumulated in this comparatively short period of time, giving almost unlimited scope to the intellect of man to interpret nature by means of induction.

EXPERIMENTATION

While a great fund of knowledge has thus been acquired by means of observation, this alone would be of little use in

discovering the causes and laws connecting these facts, were it not for the method of experimentation instituted by scientists to analyze and clarify the data of observation. An *experiment* is the *observation of phenomena under selective and controlled conditions*. Its purpose is obvious. The great number of causes and effects intermingled promiscuously in any particular occurrence makes it so extremely difficult to assign a specific cause. For any single effect, that a simplification of conditions is not only advisable but necessary. Unknown causes may always be at work in a given event, and a selective arrangement of conditions will more readily disclose the presence or absence of such causes. At the same time irrelevant facts, which might obscure the issues, are thereby eliminated, making the results more certain. By shifting the various factors which come into consideration as possible causes and arranging them in different experiments, the 'antecedents' will be gradually reduced, until one single 'antecedent' is left to account for a particular effect; and the sole cause of the phenomenon is thus discovered and proved.

The cosmic forces of nature, of course, are beyond the control of the scientist. Man cannot, for instance, interfere in any way with the movement of the stars and planets or with earthquakes, volcanic eruptions, tidal waves, and cyclones. In such cases repeated observations and the collection of cumulative data alone can lead the scientific mind to definite conclusions as to the underlying causes and effects. At times, however, exceptionally favorable circumstances may bring about a natural conjunction of

conditions which partake of the character of scientific experiment; such cases are called *nature's experiment*. Thus, a total eclipse of the sun, observed from some special vantage point, may reveal many facts which can be utilized to test a particular theory; in this manner the last solar eclipse was made the occasion of verifying certain predictions of Albert Einstein regarding the nature of light as required by his theory of relativity. Recent balloon ascensions into the stratosphere, for the purpose of determining the barometric pressure, temperature, direction and velocity of winds, cosmic rays, etc., are of a similar type. Such instances, of course, are not cases of really controlled phenomena; the scientists merely select a favorable standpoint for their observations.

Scientific experiments, in the ordinary sense, are different. Here the conditions are artificially arranged according to a definite plan and purpose. When variable quantities of chemical substances are placed together in a retort and subjected to different acids, with the temperature raised or lowered at will, then this is a scientific experiment. Similarly, when the bacteriologist inoculates a guinea pig with a certain virus, he can observe the reactions of the living system of the animal in a way which would be impossible by ordinary observation. So, too, Benjamin Franklin with his famous kite experiment furnished definite evidence that the nature of lightning is identical with the electricity produced by the electrical machine in a laboratory. Joseph Priestley, on August 1, 1774 heated mercuric oxide and observed that the 'air' or gas emanating from it aided combustion and facilitated

breathing. Antoine-Laurent Lavoisier, shortly after, showed that in producing mercuric oxide a certain portion of air was absorbed in the process and that now the air was no longer fit for respiration or combustion; from this he concluded that atmospheric air is composed of two different, and even opposite, natures, and the active portion he named 'oxygen': these experiments by Priestley and Lavoisier formed the real starting point of modern chemistry. When Louis Pasteur, in a series of experiments on lactic-acid fermentation, discovered that the souring of milk was due to a germ, he pointed the way for the proof that all fermentation, decomposition, putrefaction, and contagious diseases were the result of microbes; he thereby laid the foundation for modern bacteriology and revolutionized the treatment of diseases. In these and similar cases a selective and scientifically controlled simplification of conditions was arranged, in order to eliminate all irrelevant 'antecedents,' so that the *real cause* of the phenomenon could be discovered: it was scientific induction by means of *experimental observation*.

Two ideas dominate the whole procedure of experimentation. The one is negative and the other positive. The *negative idea* or principle, is this: *whenever a phenomenon can occur without a certain 'antecedent' being necessarily present, this 'antecedent' is in no way the cause of the phenomenon in question*. This is evident. Every effect must have an *adequate* cause, or it would be without a sufficient reason for its existence. Now, a phenomenon of nature is an effect; hence, it cannot occur, if its cause were absent. If, then, a phenomenon does occur, its *cause must*

be present. When, therefore, a certain 'antecedent' is not present, and the phenomenon occurs notwithstanding its absence, then this particular 'antecedent' can in no way contribute to the production of the phenomenon, and it is not its cause. The *positive idea* or principle is the reverse of the foregoing: *whenever a certain 'antecedent' must be present, so that the phenomenon in question will not occur without it, this 'antecedent' is the total or partial cause of this particular phenomenon.* This also is self-evident. Physical causes are necessary causes, in the sense that, when they operate, they must produce their effect. If, then, the presence of a certain 'antecedent' is so necessary for a phenomenon, that the latter cannot occur without the former, then it can only be because the 'antecedent' contributes to the production of the phenomenon in a necessary way; in other words, its presence is required as a *cause*. If this particular 'antecedent' were not a real cause of the phenomenon, there is no reason why the phenomenon should not be able to occur without it.

It will, therefore, be the aim of the scientist to vary his experiments in such a fashion, that all extraneous and nonessential factors are eliminated, leaving only those which are the actual cause. Herein, of course, lies the real difficulty of induction. A scientist may eliminate a hundred 'antecedents,' and the cause of the phenomenon may still be entirely hidden from view. From the beginning of mankind physicians have been groping in the dark for the causes of contagious diseases. They sought these causes in air and water and sky and star and evil spirits and in the nature of the animal body itself. The real cause eluded their

most diligent search, until the immortal genius of Pasteur found it in the sub-visible microbes. His discovery was not the result of endless experiments in all directions. He made no attempt, for instance, to eliminate sky and star and evil spirits; even air and water and the animal body itself never formed a direct part of his calculations and experiments. After having established the fact that bacteria were responsible for the fermentation observed in milk, beer, and wine, his imaginative genius leaped to the idea that *possibly* bacteria were also responsible for contagious diseases. With this thought in mind, he arranged *his experiments* either to prove or disprove his supposition, and his experiments resulted in the epoch- making discovery that his supposition or hypothesis was correct.

HYPOTHESIS

This brings us to another important phase of induction, the *hypothesis*. An hypothesis is the *provisional explanation of a phenomenon, based on probable arguments, until verified (or disproved) by subsequent evidence*. An hypothesis is not a mere guess or an arbitrary opinion without some foundation in fact. There must be something in the nature of the things or in the circumstances of the facts which prompts the mind to assume that a causal connection exists. An hypothesis, therefore, is a justifiable assumption which lends itself to a tentative explanation of the fact or law, so that it can be used as a guiding norm in making observations and experiments; these observations and

experiments will then either prove or disprove the assumption.

Thus, the experiments of Priestley and Lavoisier led to the hypothesis that air consists of more than one sort of gas; subsequent experiments proved that it contains oxygen, nitrogen, neon, argon, krypton, xenon, and other gases. The hypothesis that lightning is identical with electric discharges was based by Benjamin Franklin on the similarity of facts. that both give light, have the same color, proceed in an irregular direction, are swift in their motion, are conducted by metals, explode with a crackling noise, subsist in water or ice, split bodies apart, kill animals, fuse metals, ignite inflammable matter, are accompanied by a sulphurous smell. His famous kite experiment then proved that his conjecture was true. Pasteur, while studying lactic fermentation (the souring of milk) observed a cloudy deposit in the milk, which increased as fermentation progressed. Upon examination, this deposit was seen to consist of small rod-like corpuscles, which spread by fission. He thereupon *assumed* that the fermentation was caused by these microbes and made an exhaustive series of experiments to verify this hypothesis; he eventually established the fact of this cause beyond a shadow of a doubt. And when Pasteur extended this hypothesis of micro-organic causality to wound infections and contagious diseases among animals and men, proving his contention by a convincing array of factual evidence, he became the originator of modern aseptic surgery and bacteriological medicine. His discoveries thereby made him one of the greatest benefactors of humanity.

There are two *kinds of hypothesis*: the hypothesis of cause and the hypothesis of law.

The *hypothesis* of cause, as the name implies, is used to establish the causes which contribute toward the *production* of a phenomenon. The hypotheses mentioned above belong to this class. The conquest of many diseases has been made possible through the persistent experiments of scientists, following a reasonable hypothesis of cause. Pasteur's immortal work in connection with chicken pox, anthrax, rabies, and other infectious diseases was the result of such an assumption. In India alone more than a million people died yearly of malaria; its cause had been sought for centuries in the poisonous vapors of swamps. Dr. C. L. Laveran, after intensive study, became convinced that it originated in a germ and succeeded in discovering the parasite in the blood of the victims. Looking for the cause which introduced the germ into the blood stream, Sir Patrick Manson drew up the hypothesis that mosquitoes were the carriers. Sir Ronald Ross eventually traced the complete life-cycle of the malarial germ in the body of the mosquito and in man, and so the problem was solved.

One of the most startling instances of the use of an hypothesis of cause in scientific induction was the discovery of the planet Neptune. After the discovery of the planet Uranus by Herschel in 1781, its orbit was mapped out by astronomers, and the exact position of Uranus along this orbit at different periods of time was carefully estimated. But the planet insisted on being early or late in its schedule at various points of its orbit. The hypothesis finally prevailed that another unknown planet was exerting gravitational

influence on Uranus. Two mathematicians, Adams and Leverrier, calculated the exact position of this unknown planet, and on September 23, 1846, the astronomer Dr. Galle discovered it through his telescope in the exact spot which the mathematicians had predicted. The planet was given the name of Neptune.

Another interesting case is that of Pierre and Marie Curie. Up to this time thorium and uranium were the only radioactive substances known. Testing some pitchblende, Madam Curie noticed that it showed four times more radioactivity than the uranium would ordinarily produce; hence, she assumed the existence of a more powerful substance. After painstaking experiments she and her husband discovered radium.

When scientists formulate an hypothesis in an attempt to explain the *manner in which the causes of a phenomenon operate*, then such a conjectural expression is styled an *hypothesis of law*. The cause may have been previously discovered, and science now desires to know the way in which this cause operates; or, the cause may be so obscure as to defy discovery, and science is satisfied to know the law of operation, leaving the exact nature of the cause to future determination. Thus, no one knows the nature of gravitation as a cause, but Newton, basing his hypothesis of gravitation on Kepler's laws of motion, formulated the law of gravitation, stating that all bodies in the universe tend to move toward each other with an acceleration that varies directly as the product of their masses and inversely as the square of their distance. When Gregor Mendel, Abbot of Brönn, experimented for eight years on the hybridization of

garden peas and other plants, he wished to determine the laws of heredity which perpetuate certain properties from generation to generation, and the results of his experimental induction are now called the Mendelian Laws of Heredity. The active causes of heredity are still a much-disputed problem. It will be readily seen, however, that an hypothesis of law, even when it leads to the discovery of the actual laws of nature, will never be complete until an hypothesis of cause leads to the final discovery of the causes themselves whose operations constitute the physical law. The knowledge of the causes are the real scientific explanation of the phenomena; the laws are merely a formula which express their mode of operation.

Scientists often speak of a *working hypothesis*. Such an hypothesis is either one of law or of cause, as just described. There is no essential difference between this and the others; it is merely a difference of degree, in as much as a *working* hypothesis is based on very insecure grounds. It is used in cases where the known facts of a phenomenon are very few or very uncertain or very complex or very obscure. Rather than go along in observation and experiment without any guiding norm, some sort of possible or probable explanation is assumed, even though it is understood that there are few facts on hand to support this explanation. If subsequent observations and experiments increase the probability of this assumption, it becomes an hypothesis of law or cause in the strict scientific sense. Thus, ether as an all-pervading medium, filling all space, is assumed as a working hypothesis to explain the transmission of light, heat,

electricity, and gravitational force throughout the universe. No experiments have ever proved, its existence in any form, but some such medium seems a necessity as a carrier of interstellar energy. The facts of telepathy are so uncertain and obscure that their explanation by means of 'brain-waves,' 'thought- transference,' or 'emotional hypertension' is at best only a working hypothesis; the very nature of telepathy makes it difficult to subject it to the experiments of exact science. Such an hypothesis, however, has its value, because it gives the scientists a method of approach which may eventually lead to definite results. It is claimed that Kepler used no less than nineteen different working hypotheses, before he was able to explain the movements of the planets; the very fact that he discarded so many as inadequate excluded them as possible explanations and gave added proof to the Copernican Theory.

The *stages of certainty* which accompany induction are as follows: first, a phenomenon or group of related phenomena is *observed*; second, a *working hypothesis* is set up; third, as the working hypothesis explains more and more phases of the phenomena and is supported by a greater number of experiments, it becomes a *scientific hypothesis* of cause or law; fourth, when the hypothesis is considered to have reached a point where it gives a satisfactory explanation of the entire phenomenon or group of phenomena, it is a scientific theory; fifth, when the theory is positively demonstrated without any possibility of error, it becomes a *scientific fact or law*.

RULES FOR INDUCTIVE METHOD

An hypothesis must, of course, be verified. As such, it gives us only a *probable* cause and opens up a line of investigation. But the *real* cause must be determined by careful observation and, if possible, by repeated experiments. Opposing hypotheses must be proved to be false and thus eliminated as explanations. The proof of an hypothesis is in most cases a very difficult procedure, because most phenomena are an intermixture of many causes and effects, and to assign a particular effect to a particular cause is often a problem that will tax the ingenuity of the sharpest minds. The *rules of method* used in scientific induction are simple enough to state and understand, but their application to the concrete phenomena of nature is by no means an easy matter. The two *basic rules* which underlie all induction are the ones stated above: Nothing can be the cause of a phenomenon which can be absent when the phenomenon occurred; and nothing can be the cause of a phenomenon which can be present when the phenomenon did not occur. In the first case we would have an effect without an active cause, and in the second case we would have an active cause without an effect. John Stuart Mill has given this double rule a more explicit expression, and it is customary to follow Mill's Methods.

The Method of Agreement: "If two or more instances of the phenomenon under investigation have only one circumstance in common, the circumstance in which alone all the instances agree is the cause (or effect) of the given

phenomenon.” This canon is but a different formulation of the general rule that ‘nothing can be the cause (or effect) of a phenomenon which can be absent when the phenomenon occurs.’ Mill’s rule merely emphasizes the necessity of *multiplying* the instances in order to show that their relation is really causal. His phrase ‘two or more,’ though, is not very fortunate, because it takes repeated occurrence of many instances to establish a fact or law beyond reasonable doubt. Even as stated, Mill’s canon does not necessarily give us the *real* cause; it may be *hidden* in this common circumstance, but may be different from the circumstance itself. Thus, a number of people, each of whom partook of food from the same can, suffer from ptomaine poisoning; this ‘food from the same can’ is a circumstance common to them all, but the real cause of the poisoning is not the food itself, but a germ hidden in it. This, though, is true, that the same food was a necessary link in the chain of causality. Such a common circumstance will, therefore, *either be the cause itself or lead to the cause*, if investigated further. Herein lies the value of the Method of Agreement.

The argument involved in this canon may be expressed by means of symbols. In the following arrangement the *capital* letters represent the *causes* and the *small* letters represent the *effects*. Each set of symbols stands for a separate phenomenon.

ABC — abc
DAE — dae
FGA — fga
HAIJ — haij

K L A M N — k l a m n

Here we have a group of phenomena, each with three or more causes (capital letters, A, B, C, etc.) and effects (small letters, a, b, c, etc.). Each group has one effect in common ('a'), and each has one circumstance in common ('A'); everything else is different. Therefore 'A' must be the cause of the effect 'a.' From the fact that bacteria are present in all forms of fermentation, Pasteur rightly concluded that their presence was in all probability necessarily and causally connected with this phenomenon.

The *Method of Difference*: "If an instance in which the phenomenon under investigation occurs, and an instance in which it does not occur, have every circumstance in common save one, that one occurring only in the former: the circumstances in which alone the two instances differ is the effect, or the cause, or an indispensable part of the cause, of the phenomenon." This canon is an application of the general rule that 'nothing can be the cause of a phenomenon which can be present when the phenomenon did not occur.' The principle can again be illustrated by symbols as before:

ABCDE — abcde
BCDE — bcde

In this group of phenomena we notice that the effect 'a' is present when 'A' is present, and missing when 'A' is missing; all the others (B, C, D, E,) remain the same. For a scientific induction the instances would have to be repeated

through a great number of instances, before a judgment of fact or law could be considered final; but in a simple phenomenon of fact one instance may suffice. Thus, if the people who partook of a can of food suffered ptomaine poisoning, while those who abstained from that particular can of food were not ill in any way, then we observe the Method of Difference: in the one case the presence of the eating was accompanied by the presence of ptomaine poisoning, and in the other the absence of the eating was accompanied by the absence of the poisoning. The conclusion is legitimate, therefore, that the cause for this particular effect lies in the food *or in something contained in the food*. If we desire to find the *real* cause of the poisoning, we would be obliged to make a number of experiments, in order to decide whether the food itself, or some material from the container, or some germ in the food, is the actual cause. If we discovered that the poisoning food contained germs in a certain part of the food and this part caused illness, while the other *part* did not, then we would rightly attribute the evil effect to the *germs* and not to the food itself, especially if the food showed no trace of the material of which the container was made.

The Joint Method of Agreement and Difference: "If two or more instances in which the phenomenon occurs have only one circumstance in common, while two or more instances in which it does not occur have nothing in common save the absence of that circumstance: the circumstance in which alone the two sets of instances differ is the effect, or cause, or an indispensable part of the cause, of the phenomenon." Quite naturally, this Joint Method

greatly enhances the probability that we have discovered the real cause, or at least that circumstance which in some way contains the real cause; otherwise it would be impossible for the effect to be always present when this circumstance is present, and absent when this circumstance is absent. The following symbolic representation illustrates the point:

Agreement

ABC — abc

DAE — dae

FGA — fga

HAIJ — haij

KLAMN — klamn

Disagreement

BE — be

CFG — cfg

DJK — djk

HMNL — hmnL

MIGK — migk

In this first group of instances we find that amid all differences 'A' and 'a' are always found together; that already is a strong argument to consider 'A' the cause of the phenomenon 'a.' In the second group, *when compared with the first group*, we notice that the phenomenon 'a' never appears in a single set, and neither does 'A' appear; hence, we rightly conclude that the presence of 'A' in the Agreement group is responsible for the appearance of 'a,'

and that the absence of 'A' in the Disagreement group is responsible for the non-appearance of 'a': consequently, 'A' is either the cause of 'a' or at least an indispensable part of the cause.

The 'guinea and feather' experiment can be used to show the Joint Method. According to the laws of gravity all bodies should fall with an equal velocity; but a feather will be slower in reaching the ground than the coin. The hypothesis is formed that the *resistance of the air* upon the larger surface of the feather is the cause of its slowness. Placing both coin and feather in a tube filled with air, we observe that the fall of both is unequal in velocity; and this repeats itself as often as the experiment is made. So far we have the Method of Agreement. Next we exhaust the air from the tube, and now both reach the bottom at the same moment; this also happens as often as the experiment is repeated. And the same is true of other gases. In all these cases it is the presence of the air (or other gases) which causes the difference of velocity, and the only recognizable reason would appear to be the resistance exerted upon the larger surface of the feather. Hence, by the Joint Method we conclude that the *resistance of the gas* is the cause of this phenomenon of the difference in velocity between the guinea and the feather.

Method of Residues: "Subduct from any phenomenon such part as is known by previous inductions to be the effect of certain antecedents, and the residue of the phenomenon is the effect of the remaining antecedents." Strictly speaking, this canon would merely prove that there is *some cause* still to be sought, in order to explain a certain

phenomenon; it would not necessarily help us to designate a *specific* cause, unless this particular cause is *the only one left*. In most cases the phenomena of nature are not so simplified in character as to permit such a definite conclusion; it would, however, spur the scientist on to renewed investigation. The canon may be expressed in the following symbols:

$$BCX — bca$$

If we know that 'B' is the cause of the phenomenon 'b,' and 'C' is the cause of the phenomenon 'c,' then it naturally follows the 'X' must be the cause of 'a'; then 'X' would be 'A,' and the formula would become 'B C A — b c a.'

The discovery of Neptune by Adams and Leverrier is a case in point. The exact position of Uranus at any given time along its orbit was definitely calculated. The fact that the planet was sometimes ahead and sometimes behind its schedule was a residual effect. This phenomenon did not, of course, reveal the *specific* cause of this effect, but it led to the definite *assumption* that another planet was exerting gravitational attraction upon Uranus; acting on this assumption, Adams and Leverrier calculated the position of the new planet (Neptune) and so it was discovered. Similarly, Lord Rayleigh and Professor Ramsay had observed that nitrogen obtained from various chemical compounds had a weight of 2.2990 grams, while 'atmospheric' nitrogen had a weight of 2.3102 grams. This residual phenomenon of the discrepancy in weight led eventually to the hypothesis that some other element was

united to nitrogen derived from the air. Extensive experiments finally revealed a new chemical element, argon, as the cause; the difference of weight belonged to argon.

Method of Concomitant Variations: “Whatever phenomenon varies in any manner whenever another phenomenon varies in some particular manner, is either a cause or an effect of that phenomenon, or is connected with it through some fact of causation.” This means that nothing can be the cause of a certain phenomenon when it remains constant while the phenomenon varies, or varies while the phenomenon is constant, or varies in an entirely different manner from the phenomenon; but if both, factor and phenomenon, are always constant together, and always vary together, and the degree of variation between them is the same, *no matter whether the other factors in the case vary or remain the same*, then there exists a causal relation between these two. Symbolically the principle can be expressed as follows:

$$A_1 \ B \ C \text{ — } a_1 \ b \ c$$

$$A_2 \ B \ C \text{ — } a_2 \ b \ c$$

$$A_3 \ B \ C \text{ — } a_3 \ b \ c$$

Since ‘B C’ and ‘b c’ remain the same and ‘A’ and ‘a’ vary in the same manner throughout, ‘A’ must be the cause of ‘a.’ The variations of the tides coincide exactly with the variations of the moon; hence, it is concluded that the gravitational attraction of the moon is responsible for the tides. The periodic variations of the tides had been

connected for many centuries in the minds of observers with the periodic variations of the moon, but that did not explain in what way the moon was responsible for the tides. Newton's Laws of Gravitation gave an explanation of the fact; but no one knows the precise nature of gravitational force, and so the real cause of the moon's influence on the tides is still a mystery.

AN EXAMPLE OF INDUCTIVE METHOD

At bottom there are but two methods of induction: the Method of Agreement and the Method of Difference. The others are variations of these two. The basic principle of reasoning underlying all inductive methods is the *proper disjunctive hypothetical syllogism*:

The cause of this phenomenon is either A or
B or C or D or E — or X or Y or Z;
But it is not B or C or D or E — or X or Y or Z.
Ergo, the cause is A.

The crucial difficulty in any inductive process of reasoning consists in establishing 'A' as the real cause and eliminating 'B and C, etc.,' as possible causes. It is in this connection that Mill's Methods have value, because they help the investigator to establish one factor as the cause and to eliminate the rest. But no amount of theoretical rules of method will enable a scientist to gather the facts in a problem or show him which explanation to assume as an hypothesis or tell him what experiments to make; his

sagacity and inventive genius alone can help him here. As an example of scientific induction in its different phases we append Louis Pasteur's classic experiments to solve the problem of spontaneous generation.

The question had agitated the minds of philosophers and scientists for many centuries. Most of them considered it a fact *that life could originate* from putrescent matter *without parentage*; frogs, fishes, maggots, and germs were thus thought to derive their origin spontaneously from ambient organic matter. While this was more or less definitely disproved with regard to the frogs, fishes, and maggots, even eminent scientists were convinced that germs originated by *spontaneous* generation, without parentage from other germs. Pouchet, Musset, and Joly, in Pasteur's day, claimed to have made experiments which proved the spontaneous generation of living organisms. Pasteur was not convinced; his studies in fermentation inclined him toward the view that a germ could only originate from an existing germ. With this hypothesis in mind he began his experiments in 1860.

He placed quantities of organic substances in glass vessels. Each vessel had a long neck which extended into a curved tube. He sterilized these substances with heat, thereby expelling all air from the vessels. When the vessels cooled, the air again flowed into them, thus coming in contact with the infusion; but whatever matter was contained in the air dropped to the bottom of the curved tube and did *not reach the infusion in the flasks*. No putrefaction set in. (Method of Difference.) As soon, however, as the flasks were tilted to such a degree that

some of the sterilized substance touched this matter deposited by the air in the curved tube, life began and putrefaction set in. This proved that neither the air, nor the putrescible substance, nor the sunlight, were responsible for the observed germ-life in the flask, but *something contained in the air*. (Method of Agreement.)

He now strongly suspected that living germs were in the air. To test this hypothesis, he filtered air through guncotton and then dissolved this guncotton in alcohol and ether; his examination of this showed specimens of various organisms. His conviction grew that these germs were caught in the guncotton when the air was filtered through it. Testing his hypothesis from this angle, he sealed the neck of a flask, containing sterile broth, with a plug of guncotton; no life developed as long as the flask remained this way, but as soon as the flask was tilted, so that the broth came in contact with the cotton, it began to decay in a very short time. To show that the vegetable nature of the cotton had nothing to do with the result, he used plugs of asbestos; the result was the same.

But the *boiling* of the broth might possibly have influenced the substance in some unknown way. He now set about to determine this. Taking blood from the veins of healthy animals, he enclosed it with sterilized air in a flask: nothing happened. But as soon as this blood came in contact with ordinary air, it immediately began to decompose through the action of germs. This, of course, confirmed his hypothesis with fresh evidence. (Joint Method of Agreement and Difference.)

Pouchet objected to Pasteur's findings on the score that, if putrefaction were not due to spontaneous generation but to organisms floating in the air, the entire atmosphere must of necessity be saturated with germs. The point was well taken, because the development of life in such susceptible liquids seemed to take place anywhere and everywhere. Pasteur recognized the value of this objection and proposed to meet it. If spontaneous generation were a fact, he argued, it should occur invariably in the same putrefiable liquid, no matter where it was exposed to the air; but if the life of these organisms were dependent on other germs in the atmosphere, then *the purity or impurity of the air should make a difference*, because certain localities should be more favorable to germ-life than others. If he could prove this, his hypothesis would be strengthened. He boiled a highly susceptible broth in flasks and sealed them while they still steamed. The necks were broken in different localities, so that the broth came in contact with air, and then were immediately resealed. Of ten flasks opened in a cellar, where there was no free circulation of air, only one developed life, while of the eleven flasks opened above ground all began to putrefy. He thereupon prepared more flasks. Opening twenty of these in the town of Arbois in the country, eight became contaminated. At Salins, he opened twenty more on Mount. Poupet, over 800 meters above sea level; only five became contaminated. On the Mer de Glace, in the Alps, he used another twenty flasks; only one developed germs. His experiments showed conclusively that the purity or impurity of the air, and not the air as such, had a great deal to do with the origin of life in the broth. Hence,

he again concluded, it is not the air as such, but *the germs in the air* which are responsible. (Concomitant Variations.) Pouchet, however, would not be conquered. He made tests, similar to Pasteur's, on the sea, on the lowlands of Sicily, and on Mount Etna; upon exposure to the air, all his flasks developed life. Later on, Pouchet and his colleagues made similar experiments at the base of one of the Maladetta glaciers, about 1000 meters higher than the elevation at which Pasteur had made his. They had used four flasks, filled with a decoction of hay, and each, after having been exposed to the air and resealed, showed abundant germ-life after a short time. Pouchet's experiments offset Pasteur's, and the solution of the problem was again at a standstill. The controversy gripped the minds of the entire scientific world. Gradually, however, scientists swung over to Pasteur's side, because his hypothesis had the benefit of the Methods of Agreement, of Difference, and of Concomitant Variations, while Pouchet had merely the Method of Agreement in his favor and could not disprove the positive and negative results of Pasteur's experiments.

But how did it happen that Pouchet's flasks all developed life, no matter where and in what altitude these flasks were exposed to the atmosphere? The scientific knowledge of bacteria was still in its infancy at the time, and hardly anything beyond their mere existence was known. Thus, scientists were ignorant of the fact that certain bacteria can withstand a considerable amount of heat and still live. This happened to be the case in Pouchet's experiments. He had used an infusion of hay, a substance very difficult to sterilize, and the bacteria in this decoction happened to be

of a nature which could survive boiling. Hence, *Pouchet's infusions were never sterile in the flasks at any time*; life would develop, therefore, in every instance, no matter where and when the flasks were exposed to the air, because the germs would develop as soon as they obtained oxygen. The germs had lived in the infusion all the while. When this fact was definitely established, the question was settled; because, once this infusion of hay was really sterilized, it acted in every way like the putrescible substances which Pasteur had used in his experiments. (Method of Residues.) Pasteur had successfully settled the age-old problem.: *Nature knows no spontaneous generation; life originates from life, and a germ originates from an existing germ.* The establishment of this fact and law is one of the greatest triumphs of scientific induction.

This extended example of the process of induction, as employed by Pasteur, illustrates very clearly the application of Mill's Methods in the solution of a problem. Inductions like these are indeed the glory of science. But we also see that *induction must be climaxed by deduction.* Pasteur's studies in fermentation, in contagious diseases, and in spontaneous generation, naturally lead to the *universal law* that *life can only originate from life.* All further experiments along these lines substantiate this law. And this law now becomes a far-reaching principle of *deductive inference*, a veritable *Dictum de omni et nullo*, which is the basis of the deductive syllogism. How far-reaching this principle is, can be seen by the fact that it absolutely demands a *living* cause for all forms of plant and animal life on earth. Since, however, the earth, having been a mass of fiery liquid in the

ages gone by, was at one time sterile and devoid of life, it could no more have developed life of its own accord than could the sterilized flasks of Pasteur. A creation of life by the Living First Cause was necessary.

Thus it is that scientific induction and philosophic deduction meet in harmony to solve the riddles of the universe.

SUMMARY OF CHAPTER XIX

It is the purpose of science to discover the causes and laws of natural phenomena. This is done by induction. There are various elements that belong to induction.

1. *Observation*. It is the close *scrutiny and examination of natural occurrences*, in order to determine their causes and effects. Observation is made by the mind through the senses, assisted by mechanical instruments like the microscope and telescope.

2. Observation must be supplemented by experiment, which is the *observation of phenomena under selective and controlled conditions*. Experiments simplify conditions by eliminating all irrelevant factors, until the sole determining cause of a particular effect is found. The cosmic forces of nature cannot be controlled; but when a phenomenon of this sort is observed under exceptionally favorable circumstances, it is called *nature's experiment*. *Scientific experiments* are artificially arranged according to a definite plan.

A *negative* and *positive* principle dominates the procedure of experimentation. The negative principle is: Whenever a phenomenon can occur without a certain 'antecedent' being necessarily present, this 'antecedent' is in no way the cause of this phenomenon. The positive principle is: Whenever a certain antecedent' must be present, so that the phenomenon in question will not occur without it, this 'antecedent' is the total or partial cause of this phenomenon.

3. Another important phase of induction is the *hypothesis*: it is a *provisional explanation of a phenomenon*, based on probable arguments, until verified (or disproved) by subsequent evidence. It is the guiding norm in experimentation. There is an hypothesis of *cause*, which seeks to establish the causes of a phenomenon; and an hypothesis of law, which seeks to explain the manner in which the causes operate. A *working hypothesis* is one of cause or law, but based on insecure grounds.

4. The *rules of Method* used in induction can be formulated as follows (Mill's Methods):

Method of Agreement: If two or more instances of the phenomenon under investigation have only one circumstance in common, the circumstance in which alone all the instances agree is the cause (or effect) of the given phenomenon.

Method of Difference: If an instance in which the phenomenon under investigation occurs, and an instance in which it does not occur, have every circumstance in common save one, that one occurring only in the former: the circumstance in which alone the two instances differ is the effect, or the cause, or an indispensable part of the cause, of the phenomenon.

The Joint Method of Agreement and Difference: If two or more instances in which the phenomenon occurs have only one circumstance in common, while two or more instances in which it does not occur have nothing in common save the absence of that circumstance: the circumstance in which alone the two sets of instances differ is the effect, or the

cause, or an indispensable part of the cause, of the phenomenon.

Method of Residues: Subduct from any phenomenon such part as is known by previous inductions to be the effect of certain antecedents, and the residue of the phenomenon is the effect of the remaining antecedents.

Method of Concomitant Variations: Whatever phenomenon varies in any manner whenever another phenomenon varies in some particular manner, is either a cause or an effect of that phenomenon, or is connected with it through some fact of causation.

5. Pasteur's experiments regarding spontaneous generation are a classic example of induction.

Chapter 20

PROBABILITY

THE GOAL OF SCIENCE AND PHILOSOPHY IS THE KNOWLEDGE OF truth with certitude. In the line of knowledge the two extreme attitudes of the mind are complete ignorance and full certitude. The field between these extremes is probability. Ignorance is the absence of knowledge in a being capable of possessing it. Certitude is that state of the mind in which the mind gives a firm assent to a judgment without fear of the possibility of error, due to recognized valid reasons. *Probability*, considered *subjectively*, is that state of the mind in which it decides for the truth of a judgment, but with fear of the possibility of error. Considered *objectively*, probability is that condition or quality of things and facts, when present to the mind, which enables the mind to decide for the truth of a judgment concerning these things and facts, but with the fear of the possibility of error.

It is impossible for us to know all things with certitude. About most things our knowledge amounts to nothing more than probability. There are, of course, degrees of probability, depending upon the extensiveness and reliability of our knowledge of things and facts. Nature is so

complex and the methods of research are frequently so difficult, that science must be satisfied with *approximations* to truth and certitude. It may happen that the evidence for a law or generalization is favorable, but insufficient; or it may happen that the evidence is so conflicting that all reasonable doubt cannot be eliminated. We then have probable truth.

In its search for truth, science makes use of various forms of argumentation and method which lead to results which are probably true. Such are: *analogy, statistics, averages, testimony, circumstantial evidence*. Their scientific value depends on a number of factors.

ANALOGY

By *analogy* we here mean that reasoning process whereby the mind concludes from the known characteristics of one thing or a group of things to the unknown characteristics of another thing or group of things because of a recognized resemblance existing between them. Mill expresses the *principle of inference* in analogy in these words: "Two things resemble each other in one or more respects; a certain proposition is true of the one, therefore it is true of the other."¹ In symbolic form the principle reads as follows: A is similar to B in many of its characteristics; A has the characteristic X; therefore, B also has the characteristic X.

For example: The Earth and Mars resemble each other in many respects. Both are planets in the same solar system; their distances relative to the sun are approximately the same; they have similar atmosphere,

seasons, temperature, and diurnal revolution. From these resemblances scientists are inclined to conclude that Mars, like the earth, is inhabited. Light, like sound, travels in all directions from a common center; both can be reflected, and the angle of reflection is equal to the angle of incidence. Sound, however, travels in waves. By analogy it was then inferred that light is also undulatory in character. From the falling of an apple through space to the ground, Newton concluded by analogy to the universal law of gravitation governing the movements of the heavenly bodies. From the variations found among plants and animals, due to the intentional selection of skillful breeders, Darwin was led to the conclusion that 'natural selection' through the struggle for existence could account for the origin and perpetuation of new species.

It should be fairly obvious that an inference of this kind can only lead to a conclusion which is probable, and not certain. If the things or facts compared were known to be perfectly alike, the conclusion would be certain. But no two things or facts are perfectly alike in all details; there are always *differences* together with resemblances. Hence, there will always be the danger of concluding to a difference rather than to a resemblance. And this danger increases with the complexity and obscurity of the things or facts compared, because in such cases the number of differences may be far greater than the number of resemblances. Hasty generalizations must be avoided.

Again, not all resemblances are important, and consequently no safe conclusions can be drawn from them. Only *significant resemblances* have value. By 'significant

resemblances we mean those which are essential or closely connected with the essence. In such instances the inference of analogy has greater force, because in all probability a causal connection exists between such resemblances, resulting in a relevancy between them. That a hundred men have a weight of one hundred and fifty pounds, does not entitle us to conclude by analogy that they have the same age or that they are equally educated. But when one hundred men graduate from the same department of a university with approximately the same scholastic standing, the inference is legitimately made that they are of approximately equal talents. In the first case, weight is not a significant resemblance, while in the second case their scholastic standing is; weight has no necessary connection with age or education, but scholastic achievement is necessarily dependent on intelligence as an effect on its cause. But even in this second case the conclusion is only probably true, because one student might put more effort into his work than another, thereby overcoming the difference of talents existing between them.

Naturally, a large number of significant resemblances will secure a greater amount of probability and bring the conclusion closer to certainty, since in that case the presence of a *similar essential connection* in the things or facts is more probable. Thus the Earth, Mercury, Venus, Mars, Jupiter, and Saturn are planets revolving around the sun in elliptic orbits, have nearly the same shape, etc. Now, the Earth, Mars, Jupiter, and Saturn possess the characteristic of rotating around an axis. This rotation is a significant resemblance together with many others. Hence,

it is inferred by analogy that Mercury and Venus also possess this characteristic of rotation around an axis. Ordinarily, one would consider the fish shape of a whale and its living in water to be significant resemblances to a fish and judge it to be a fish. But the facts that the whale breathes through lungs, brings forth its young alive and suckles them, are significant resemblances which definitely classify the whale with the mammals and not with the fish.

To distinguish between significant and insignificant resemblances will always remain the greatest difficulty in an analogical inference. A deep and extensive knowledge of scientific facts and their relative value is a practical requirement to safeguard the mind against error in an inference based on analogy.

STATISTICS

By *statistics* we understand the classification and evaluation of group phenomena by an analysis of data supplied by enumeration and measurement. The method of statistics is valuable in fields of research where a multitude of numerical units of a variable character are involved or where phenomena are the result of many independently varying factors. In instances of this kind it is extremely difficult to detect directly the laws which govern the workings of the relations existing between such units or factors. Nevertheless, a close examination of the available data, especially when the tabulation is quite complete, will reveal certain definite trends and frequencies which approximate laws.

In the natural sciences it is necessary to use *instruments of measurement*, in order to eliminate as much as possible the personal equation of the individual observers. The most refined and delicate instruments, however, are subject to changes in accuracy, due to the material of which they are constructed and to the variations of temperature, vibration, mechanical handling, etc. Absolutely exact measurements are thus impossible of attainment. Besides, the personal element of the observer and the peculiarities of his sense organs and sense reactions can never be eliminated completely, so that differences of results on the part of the observers is practically inevitable. Because of these facts, statistical averages are used to correct as far as possible the errors of instrumentation and observation. In the *biological, psychological, and social sciences* the factors responsible for events are so variable and complicated, that statistical tabulations are often the only reliable means of arriving at any definite knowledge of the origin and nature of these events. Wherever human actions with their motives and counter-motives have their play on a large scale, as in national and international movements and affairs, no individual or small group of individuals is capable of making an adequate survey of the entire field; the field must be parceled out among a large number of investigators, and their findings must be tabulated in such a manner that they can be viewed and examined with little difficulty.

The *value of statistics*, properly made, is great. They enable us to obtain a concise and comprehensive knowledge of an unwieldy mass of isolated facts by correlating them along definite lines and expressing them

in more or less exact figures. This is a simplification of material akin to the controlled selection of conditions in a laboratory experiment. The influence of personal prejudices and preconceived notions in the single investigators is thereby reduced to a minimum, thus allowing the mind to obtain more accurate and unbiased results in its analysis of the data. Then, too, statistics are often used as the foundation for predictions regarding the future course of events. Frequency tables may show that certain occurrences appear in cycles and last for fixed periods of time; this enables the scientist to forecast events with a reasonable amount of probability. Finally, statistics may disclose many relations between seemingly disparate factors. Uniformities and variations between statistical tables and figures thus reveal causal connections where ordinarily none would be suspected. In this manner important information has been obtained concerning heredity and environment, sanitation and health, food supply and population, wealth and war, poverty and crime, wage conditions and social unrest, and a host of other far-reaching problems.

The *principle of inference* in the statistical method is the inductive principle of concluding from the characteristics of a large number of parts to those of the whole. As a strictly logical procedure it is, of course, impossible to argue from the part to the whole with logical necessity what is true of some need not be true of all. But when the enumeration is practically complete, or when it can be fairly well determined that the characteristics in question are fundamental, such a conclusion carries with it a very high

degree of probability. This form of argument is based mainly on the Method of Concomitant Variations. Such concomitant variations presuppose a uniformly varying causal connection between events and the factors underlying them.

As for the *method of making statistics*, the following steps are necessary. First, the problem must be defined with precision, so that only those investigations will be made which are germane to the specific problem in question. Then the material must be collected according to the requirements of this problem and chosen from as wide a field as possible, so that the facts are truly representative of the class. When the collection of the material is completed, the data must be tabulated in a manner which coincides with the purpose of the chosen problem. Next, a summary must be given of the significant features of the tabulated material in a clear, concise, intelligible survey; to facilitate matters, charts, graphs, diagrams, and similar devices are often used. Finally, the statistician must present a critical analysis of the data, showing what conclusions follow necessarily from the facts and figures obtained.

The last point is most important: data must be *correctly interpreted* in order to be of any value for science. Mere enumeration and tabulation do not suffice. It is the purpose of all statistics to discover determining factors and their relations hidden beneath the cold figures of tables, so as to enable the mind to formulate generalizations and laws. Figures do not explain themselves, and they are often misleading. On the basis of statistical figures alone one might be inclined to conclude that juvenile delinquency is

greatly on the increase, because more youths find their way into the courts now than twenty-five years ago. This conclusion, however, would be hasty. Formerly, the policeman on the beat handled youthful delinquency in a sort of unofficial capacity, because few juvenile courts were in existence at the time and it was deemed inadvisable to hale such delinquents before the criminal courts. Juvenile courts were instituted more for the prevention than for the punishment of youthful misdemeanors, and this might account for the greater number of delinquents now brought before the judge. Similarly, the fact that the vital statistics of a town reveal a large increase in the death of school-age children during a certain year would not necessarily warrant the conclusion that sanitary conditions must have been poor. This increase in deaths might be the result of an earthquake or an explosion. Only if the data are correctly understood and interpreted will they lead to reliable results.

The *dangers of the statistical* method are many. Chief among them are the following: Looseness in the definition delimiting the problem may vitiate the entire investigation. If the various statisticians understand the nature of the problem in different ways, it is obvious that they will view the material from diverse standpoints, and the collected data will not present a true picture of the problem they desire to solve. The selection of data from a field which has been arbitrarily restricted is another danger, because then the data will not cover the real problem in its entirety. There is danger also in drawing conclusions from poorly or incompletely selected data; in this case the data would not

be truly representative of all phases of the problem, especially if the problem be extensive and complicated, and the generalizations deduced from the data might be faulty and misleading. Finally, there is always grave danger that the pre-conceived notions and the desires of the investigators may unduly influence their choice and interpretation of the data. If they set out with the explicit or implicit purpose of proving some pet theory, their purpose will probably bring about a manipulation of the material so as to make the results coincide with their views. There may be no deliberate intention of corrupting the evidence and deceiving others, but the investigators themselves may be deceived into placing a construction upon the data which the data do not inherently warrant.

When, however, these dangers are avoided and the material is relatively complete and representative, statistics are a powerful instrument of knowledge in coordinating and understanding large masses of group phenomena.

AVERAGES

Closely allied to statistics is the *method of averages*. By an average' we understand the mean proportion, medial sum or quantity, made out of unequal sums or quantities. Since statistical operations are based on sums and quantities, it is obvious that averages play an important part in statistical calculations. A knowledge of the methods of computing averages will be, therefore, a valuable aid for science in arriving at probable results.

The *purpose* of averages should be plain from their very nature and use. Being a mean proportion, medial sum or quantity, they 'give us a synoptic representation of a group or mass of unequal sums or quantities, thereby making the problem more intelligible. They enable us to carry out extensive comparisons between one group and another, so that generalizations can be made more easily and more quickly. By reducing group figures to compact units, they simplify lengthy calculations.

Depending upon the kind of problem to be solved, various *kinds of averages* are used. The simplest is the *arithmetical average*, by which term we designate the sum of the particular items divided by their number. Let us suppose that the single grades on a student's report card for the first semester are 75, 83, 84, 86, 90, 92, and 92. The sum of all items is 602, and the number of items is 7; by dividing 602 by 7 we obtain the average of 86. Averages of an arithmetical nature may lead to important scientific results. We have an instance of this in the experiments of Rayleigh and Ramsay, while making measurements of the weight of nitrogen obtained from chemical compounds and from the atmosphere (see p. 311). The average weights obtained from the two sources varied so consistently and uniformly, that they eventually led to the discovery of argon.

Sometimes *weighted averages* are used. When the term 'weighted' average is used, we mean thereby an average whose particular items have been multiplied by certain weights before their addition, and this sum is divided by the sum of the weights instead of by the number of items. Weighted averages appear in two types: in the one kind the

averages of separate groups with unequal numbers of items have already been taken, and then an arithmetical average is taken of the combined groups; in the other kind the averages are weighted in proportion to their relative value and importance, and then an arithmetical average is taken of them all. An example of each will make the matter clearer.

A certain factory has three departments. One employs 20 men at an average of \$20 a week; the second employs 15 men at an average of \$25 a week; the third employs 100 men at an average of \$22 a week. The simple arithmetical average of these three averages (\$20, \$25, and \$22, divided by 3) would be \$22.33. It is felt, however, that this average does not give a true picture of the wage average, because unequal numbers of men are employed in the different departments. The averages are therefore 'weighted' by the total number of employees: 20 men at \$20 earn \$400 a week; 15 men at \$25 earn \$375 a week; 100 men at \$22 earn \$2,200 a week, making a total of \$2,975 a week for all workers. This sum, divided by the total number of workers, makes an average of \$22.04 for each man. This is an example of the first type of weighting an average.

In the second type, as stated above, weights are added corresponding to the relative importance of the various items listed. Let us suppose that we desire to estimate the change in the cost of living in 1936 as compared to the year 1926. The price per item or unit in 1926 will be taken as par or 100. In proportion, then, the relative prices per item in 1936 (let us assume) are as follows: beef 95, flour 120,

cotton 60, silk 150, jewelry 50 Adding these figures and dividing the sum by 5, we obtain the arithmetical average or mean of 95; to all appearances the cost of living has gone down in 1936. This, however, hardly seems a reasonable way of viewing the problem, because the importance of these various items for daily life is unequal. Hence, 'index numbers' are attached to these figures, representing the estimated relative value of each to the other, so that (let us again assume) beef is estimated at value 8, flour at 12, cotton at 6, silk at 2, and jewelry at 1. We now obtain the following results:

Beef....	.95	x 8	=	760
Flour	120	x12	=	1440
Cotton	60	x 6	=	360
Silk..	150	x 2	=	300
Jewelry	50	x <u>1</u>	=	<u>50</u>
.....	29			<u>2910</u>

If we now divide the sum of 2,910 by 29, we obtain the weighted average of 100.3 and thus it will be seen that the general cost of living is nearly the same in both years. The difficulty, and also the danger, of this type of weighted averages lies in the assignment of proper index numbers; if carefully handled, however, such averages can be of great assistance in solving economical, social, psychological, and educational problems.

Another type of average is the *mode*. By this we understand the quantity or item which appears with greatest frequency in a group. The mode represents the

general type or 'run' of a group. When we speak of the 'average man,' the 'average mother,' the 'average student,' the 'average politician,' the 'average shoe,' the 'average girth measurement,' the 'average hat size,' etc., we mention the 'mode' of each class. This sort of average is important, when it is merely a question of the most frequent size of item in an unequal series. A clothier may know, for example, that of 100 middle-aged men who apply for a ready-made suit of clothes usually 2 have a girth measurement of 32, 6 of 34, 12 of 36, 20 of 38, 45 of 40, 6 of 42, 4 of 44, 4 of 46, and 1 of 50. In this series the item of 40 occurs 45 times: this is the 'mode' of the group, and the clothier will naturally order the greatest number of suits of this particular size rather than an arithmetical average of all sizes. Frequently, but not always, the mode and the arithmetical average will coincide.

Finally, there is the type of average called the *median*. It is the middle quantity or item in a series arranged according to magnitude. In the case of odd numbers, one number will obviously occupy the central position and can easily be detected. Thus, among seven students whose grades are arranged as 50, 60, 75, 82, 86, 90, and 94, the fourth number, or 82, will be the median of the series. In the case of even numbers, the median will be the average of the two which are the middle quantities. Among eight students whose grades are 50, 60, 75, 82, 86, 90, 94, and 95, the average of 82 and 86 will be the median item, and that is 84. This type of average is frequently used in grading mental capability, because any other sort of measurement of group mentality is inaccurate.

TESTIMONY

It is the endeavor of every scientist to establish all his knowledge by means of direct and irrefutable observation. But this is an ideal which no scientist can realize; the field of knowledge is so vast that the short span of his life makes such a personal investigation and verification impossible. He must rely on the observation and the testimony of others for much of his knowledge and for the proofs which make his knowledge certain. *Testimony* or testimonial evidence is the information or evidence obtained from competent and reliable witnesses. These witnesses, therefore, have observed the facts in question, are competent mentally and physically to judge of the true state of the facts observed, and are reliable in giving a trustworthy and truthful account of their observations. Under such conditions testimonial evidence will lead to certitude, or at least to a high degree of probability.

Unfortunately, the evidence supplied by direct witnesses is not always without flaws. Such evidence is based on *perception, memory, and narration*. The frequency of error in perception is notorious. Many persons are witnesses to the same fact; but they react differently to the situation encountered, and in many cases their judgment is colored by emotion and associated ideas. Memory, too, is faulty. Unless a report is fixed in writing during the process of observation or immediately after, details fade, and foreign elements soon become mixed with the observed data to such an extent that the evidence of the witness must be received with critical reservations. Courts of law and

experiments along these lines prove this beyond dispute. The element of language involved in narration presents added difficulties. Not all persons are capable of adequately expressing their observations in correct language so as to exclude all ambiguity and inexactitude; and oftentimes language lacks the proper words to describe the thing or event observed. Hence, testimonial evidence must be weighed and sifted carefully before it can be accepted in its entirety.

All testimony, even of truthful witnesses, must be submitted to a number of *logical tests*. First, the testimony of a witness must be self-consistent. By this is meant that no part of the testimony is allowed to contradict another part. Facts and things cannot contradict themselves; they simply are what they are. Hence, a report concerning them must also be self-consistent or non-contradictory. A contradiction in the testimony, therefore, shows that either the observation of the witness was inaccurate or that his memory played him false. In either case the testimony becomes more or less unreliable, depending upon the nature and magnitude of the discrepancy. Again, the testimony must be in agreement with other established facts, otherwise a contradiction would exist in the very facts themselves; facts, however, just because they are facts, are necessarily true. It stands to reason, therefore, that the evidence of a large number of independent and mutually unacquainted witnesses will greatly strengthen the evidence of the testimony of each; on the other hand, contradictory testimony on the part of a number of reliable witnesses casts a doubt on the entire evidence. Finally, the

testimony must be in accordance with the known laws of the intrinsic possibilities of the event. Something intrinsically impossible cannot happen; hence, no amount of testimony can establish such an event. It is possible, of course, that the physical laws of nature be suspended through divine interference, and it is also possible that such events be adequately observed.

The farther, however, such events recede from the ordinary course of nature, the more competent the witnesses must be.

If the evidence supplied by the witnesses survives these tests, it may be accepted as true. A critical attitude, however, must always be maintained.

CIRCUMSTANTIAL EVIDENCE

It is not always possible to obtain direct observation or direct testimony. In many instances, however, *circumstantial evidence* may point the way to the solution of a problem of fact. By circumstantial evidence we understand those relevant circumstances or facts which enable us to draw legitimate inferences to some principal fact, which fact then explains the existence and presence of these relevant circumstances or facts.

The main occasion for the use of circumstantial evidence is found in the criminal courts. Criminals are usually not desirous of having eyewitnesses present to observe the commission of a crime. They hope to escape detection by the absence of witnesses who may give direct evidence against them in a court of law. It is in the absence of

witnesses that circumstantial evidence may prove to be the means of convicting the criminal. In some instances circumstantial evidence may be of even greater value than the testimony of direct witnesses. The commission of the crime may be done so quickly, that the event is past before the witnesses have a fair opportunity to observe what has occurred; errors of observation or impression may occur which lead to distorted judgments. Contrariwise, circumstances may be detected which permit of thorough and prolonged study in the light of cold reason, fixing the identity of the criminal beyond reasonable doubt.

Circumstantial evidence is in the *nature of a hypothesis*: a crime was committed, and there must be a criminal or criminals who committed it. Various possibilities are present as to the identity of the criminal or criminals, but only one of these possibilities can be actually true. The logical procedure, therefore, is to eliminate all suspects (possible causes) except the guilty party or parties (the true cause), by showing that the relevant circumstances of the case cannot be accounted for under any other supposition. The sole cause of the crime is thus inferred from the circumstantial evidence surrounding the occurrence of the crime.

As a rule, a number of significant and relevant circumstances must unite in order to furnish *convergent evidence*. The greater their number and the more varied their character, the higher is the degree of probability that they contain the correct solution of the problem. Let us assume that a murder was committed during a bank robbery. As the robber is about to leave with the money, the

cashier attacks him and is shot. In the shuffle the robber drops his eyeglasses. He escapes, but neglects to pick up his eyeglasses. The police find them, trace them to the oculist who prescribed them, and thus discover the owner. When apprehended, the man is observed to be without the eyeglasses he is known to use. The money of the bank is also found, hidden in his room. Ballistic experts then prove that the bullet which killed the cashier was fired from the gun carried by the accused on his person at the time of his apprehension. Any one of these relevant circumstances points unmistakably to this man as the robber and murderer, but the convergence of evidence places his guilt almost beyond the possibility of doubt.

At times, however, a *single relevant circumstance* may suffice to settle the problem. A man, for example, is found murdered, with a knife in his heart. Upon examination, a complete set of distinct fingerprints is found on the haft of the knife, and these fingerprints are those of a known criminal. Since it has been established that fingerprints are distinctly individual, it is clear that this known criminal must have been the last one to have handled this knife. He is, therefore, the murderer, and a conviction should follow.

Obviously, a degree of probability amounting to practical certainty will be reached when strong circumstantial evidence is linked with the evidence of reliable direct testimony. In such a case the chances of error are reduced almost to the vanishing point. That circumstantial evidence is exposed to the serious danger of abuse and misinterpretation, need hardly be mentioned. Its strength

lies mainly in the *cumulative force* of a number of convergent facts all pointing directly to one source.

Such, then, are the methods of reasoning employed by scientists and logicians in acquiring probable knowledge. Where strict demonstration is impossible of attainment, the methods of analogy, statistics, averages, testimony, and circumstantial evidence will be found to supply valuable information of a more or less probable character. All these methods are forms of scientific induction.

SUMMARY OF CHAPTER XX

Much of our knowledge is only probable, not certain. The methods employed to obtain probable truth are analogy, statistics, averages, testimony, and circumstantial evidence.

1. *Analogy*. By this is meant the reasoning process whereby the mind concludes from the known characteristics of one thing or group of things to the unknown characteristics of another thing or group of things because of a recognized resemblance existing between them. Only significant resemblances have value.

2. *Statistics*. Statistics are the classification and evaluation of group phenomena by an analysis of data supplied by enumeration and measurement. The principle of inference is the inductive principle of concluding from the characteristics of a large number of parts to those of the whole. To be of real value, the data must be correctly analyzed and interpreted.

3. *Averages*. By an 'average' we understand the mean proportion, medial sum or quantity, made out of unequal sums or quantities. There are various kinds of averages: arithmetical average, weighted averages, the mode, and the median.

4. *Testimony*. Testimony or testimonial evidence is the information or evidence obtained from competent and reliable witnesses. Since testimony is based on perception, memory, and narration, the personal equation of the witness frequently involves error. Such evidence, to be acceptable, must be self-consistent, must be in agreement

with other established facts, and must be in accordance with the known laws of the intrinsic possibilities of the event.

5. *Circumstantial evidence*. It consists of those relevant circumstances or facts which enable us to draw legitimate inferences to some principal fact, Which fact then explains the existence and presence of these relevant circumstances or facts. As a rule, a number of significant and relevant circumstances must unite in order to furnish convergent evidence.

Chapter 21

FALLACIES

THE ANTITHESIS OF TRUTH IS ERROR. TRUTH IS THE AIM AND GOAL of science and philosophy, and truth can be attained only by correct thinking. It is the particular purpose of logic to supply the mind with the knowledge of the laws of thought and the rules of correct thinking, so that it can proceed with safety and certainty in its pursuit of truth. These laws and rules have now been examined and established; familiarity with their technique should help the mind to avoid the more glaring errors which result from a violation of the fundamental forms in which the mind casts its thoughts in the formulation of arguments. *Formal* error should occur, therefore, far less frequently in the case of a mind instructed in logic. *Material* error is more insidious in character.

A material error may be due to the simple ignorance or the plain misapprehension of facts. Misapprehension was the reason of the belief, prevalent for thousands of years, that the sun rotated around the earth. Ignorance of the existence of microbes was responsible for the false notions about the origin and nature of many diseases. Many mistakes in everyday life are due to hasty conclusions based

on incomplete or faulty knowledge. There is no remedy for such errors except a careful study of the nature and circumstances of things. No rules of logic can hinder the mind from falling into errors of this type. Other errors, though, are *errors of argumentation*, based on the use of words or ideas which have a *deceptive resemblance to truth* and thereby lead to avoidable false conclusions. When such deceptive words and ideas are used with the purpose of misleading, the argumentation is called a *sophism*; but when this is done *unintentionally*, through inadvertence as the result of a mental slip, it is styled a simple material *fallacy*. Errors of this type are particularly dangerous in any form of argumentation, and a thorough knowledge of the various kinds of sophisms and fallacies should be of great assistance in avoiding them in our own inferences and in detecting them in the arguments of our opponents. Since logic is the science of correct thinking, it is within the province of logic to point out and explain the sources of such errors which involve a violation of some logical principle while possessing a deceptive appearance of validity.

Various attempts at a complete classification of fallacies have been made in the course of time, but Aristotle, as in most problems pertaining to logic, has made a division that serves all practical purposes. He classifies them as *Fallacies in the Language and Fallacies in the Matter*. The former rest upon the lack of preciseness in the words used to express thoughts; the latter are the result of confusion in the thing stated. Both classes have a number of subdivisions.

FALLACIES IN LANGUAGE

They are six in number: Equivocation, Amphiboly, Composition, Division, Accent, and Figure of Speech.

In the case of *Equivocation* the fallacy consists in using a *word in different meanings*. In syllogisms it amounts to a four-term construction. Here is an example: 'Spirits are immaterial substances; but whiskey and liqueurs are spirits; ergo, they are immaterial substances.' The equivocation here lies in the double meaning of the word 'spirits.' Or take this: 'All persons without baptism will be lost forever; Jews, Mohammedans, and heathens are without baptism; ergo, they will be lost forever.' Now, the word 'baptism' in the major premise means 'baptism of *water*,' and that is a fallacy, because Jews, Mohammedans, and heathens may have either a baptism of 'desire' or of 'blood' or both. The word 'baptism' is ambiguous in the major premise. When the Origenists stated that they believed in 'the resurrection of the body,' they were guilty of a sophism, because they did not mean a body of flesh but a body of aerial matter; they gave a totally different meaning to the word 'body' than the one usually implied by the term.

AMPHIBOLY IS THE AMBIGUOUS USE NOT OF A SINGLE WORD, BUT OF a *phrase or of a complete sentence*. For instance: 'This man his father killed.' One cannot tell from this sentence whether 'this man killed his father' or whether 'this man was killed by his father.' When Macbeth went to consult the

witches, they conjured various apparitions before his eyes. One said to Macbeth:

‘Be bloody, bold, and resolute; laugh to scorn
The power of man, for none of woman born
Shall harm Macbeth.’

There was a ghastly deception in the phrase ‘none of woman born shall harm Macbeth’; because, when he faced Macduff and invoked the words of the apparition, Macduff countered with the statement:

.... Macduff was from his mother’s womb
Untimely ripped.’

A similar instance is found in Shakespeare’s *Henry VI*, where the witch prophesies: ‘The duke yet lives that Henry shall depose.’ It is not at all clear whether ‘Henry shall depose the duke’ or whether ‘the duke shall depose Henry.’ It would be necessary to substitute ‘who’ or ‘whom’ for the word ‘that,’ in order to make the meaning clear; the failure to do this makes the entire sentence ambiguous.

A PROLIFIC SOURCE OF ERROR IS THE FALLACY OF *COMPOSITION* and *Division*. The fallacy of Composition consists in taking *jointly what should be taken separately*; and the fallacy of Division consists in *taking separately what should be taken jointly*. Consider the following argument: ‘Two and three are less than four; but two and three are five; ergo, five is

less than four.' The minor premise and the conclusion take 'two and three' conjointly, while the major premise takes them separately; this is therefore a fallacy of 'composition.' Because it is true that 'a man who is lying down can stand up' (in a divided sense, successively), it would be a fallacy to conclude that 'a man can therefore lie down and stand up at the same time'; this would also be a fallacy of 'composition.' Here is another instance of 'composition': 'All the angles of a triangle are less than two right angles (i.e., taken singly and separately, each for itself); but the three angles of a triangle are all the angles of a triangle (i.e., taken collectively, all together); ergo, the three angles of a triangle are less than two right angles.'

The fallacy of 'division' is the reverse: it takes singly and separately what ought to be taken collectively and conjunctively. We see this plainly in the following syllogism: 'All soldiers are an army; but General Pershing was a soldier; ergo, General Pershing was an army.' In the major premise the term 'all soldiers' is taken collectively, as a body and an aggregate; the minor premise and the conclusion then take the term 'soldier' in a distributive sense, applying it separately and singly. The same is true, in the minor premise, of the following argumentation: 'Sixteen is divisible by four; but nine and seven are sixteen; ergo, nine and seven are divisible by four.' Here is the picture presented by the prosecution to the jury: 'Blank, the accused, had threatened to kill X; an hour later he was found beside the body of the murdered X, immediately after the shot was fired, with his own revolver, still smoking, in his hand.' The jury acquits Blank on the following grounds:

Many people threaten to kill, but never do. it; the revolver may have gone off accidentally, as it often happens; the actual murderer may have stolen the gun from Blank and dropped it alongside the body after the shooting, and Blank, hearing the shot, may have hurried to the side of the murdered man and picked up the gun, which was still smoking; ergo, the evidence is not conclusive. Here the single instances, that sometimes occur separately, are considered as an explanation for a series of circumstantial evidences which must be considered collectively: it is the fallacy of 'division.' The problem of 'one straw breaking a camel's back' is a fallacy, or rather a sophism, of this kind. 'Will one straw break a camel's back?' 'No.' 'Will the second straw do it?' 'No.' 'Will the hundredth straw do it?' 'No.' 'Will the thousandth straw do it?' The numbers are thus increased. 'Will the two-millionth straw do it?' 'I don't know; I suppose so. Well and good; the two-millionth straw will, therefore, break the camel's back; but the two-millionth straw is a single straw; ergo, a single straw can break a camel's back.' Put in this form, it is a fallacy of 'division.' If each straw is placed on the camel's back and then removed, to give place to each succeeding one, then the two-millionth straw will not break the camel's back either. But if all the preceding straws are left there, then one straw, *conjointly with all the others*, will break the camel's back. But the way the argument is put, the supposition is that one single straw, taken alone, is capable of breaking the camel's back. Here a thing is taken separately which must be taken collectively: The last straw, in conjunction with, and as a part of, the whole aggregate of straws, will produce the

effect, but not as a mere unit by itself. The same argument is used to show that the pulling out of a single hair (after, perhaps, ten thousand others have been pulled out) can make a man bald.

THE FALLACY OF *ACCENT* OR *PROSODY* IS AN AMBIGUITY WHICH arises from a *false accent or false emphasis in speech*. Supposing a senator on the floor accuses a colleague of being 'an unmitigated liar.' He is asked to retract this statement as being opposed to the amenities of senatorial etiquette. He thereupon rises and says: 'I called him an unmitigated liar: it is true: and I am sorry for it.' Evidently, this is a dubious apology, and everything will depend upon the inflection of the voice in speaking the sentence. The part containing the apology can be interpreted in two ways. It may mean: 'It is true (that I called him a liar); and I am sorry for it (i.e., that I called him a liar).' But it may also mean: 'It is true (that he is a liar); and I am sorry for it (i.e., that he is a liar).' The faintest tinge of contempt in the voice will be a restatement of the original slur; but an expression of regret in the voice will make it a true apology; an indifferent enunciation will permit anyone to place either interpretation upon the words. When Cardinal Wolsey was dying, he said to Sir William Kingston: 'Had I but served my God with as much zeal as I have served my king, He (he?) would not have given me over in my old age to my enemies.' Since these words were spoken and not written, it is not at all certain whether 'he' refers to the king or to God. When the following syllogism is spoken (not written), it contains

a fallacy of 'accent': 'All who knead bread are bakers; all the poor need bread; ergo, all the poor are bakers.'

THE FALLACY OF *FIGURES OF SPEECH* IS MADE, WHEN A conclusion of *identity or similarity in meaning* is drawn between one diction and another, due to their similarity of construction. This fallacy, as can be seen by the definition, has nothing to do with tropes or 'figures of speech' in a rhetorical sense. Whoever mixes direct and logical universals is guilty of this fallacy. For instance: 'Relation is a category; but a brother-in-law is a relation; ergo, a brother-in-law is a category.' Similarly, to confuse the grammatical and real meanings of a term is an instance of this fallacy: 'Poet is a noun; but Dante was a poet; ergo, Dante was a noun.' This fallacy is also committed when one judges from the form of one word to the form of another word: 'Since the meaning of "insecure" is the opposite of "secure," the meaning of "invaluable" must be the opposite of "valuable" for the same reason.' Simply because a 'model' may be 'something made in an imitation of the real thing in life' is no reason for considering a 'model husband' nothing but 'an imitation of a real husband.' So, too, it would be wrong to argue that there must be a similarity in meaning between 'sacred' and 'sacral,' since both have the same etymological derivation. If anyone were to consider the equivocal use of a metaphor in its figurative and literal meaning as belonging to the fallacy discussed in this paragraph, because a metaphor is a 'figure of speech,' he would be guilty of this fallacy of 'figures of speech.'

FALLACIES IN THE MATTER

These fallacies do not rest upon an improper and specious use of words, but upon a *confusion of ideas and things*. They are: Fallacy of Accident; Absolute and Qualified Statements; Ignoring the Issue; Begging the Question; Consequent; False Cause.

The *Fallacy of Accident* consists in the confusion of the *accidental and essential characteristics* of a thing, so that what is affirmed of something which is adventitious to a thing is also applied to the subject itself. Not all logicians interpret this fallacy in the same way. Some give it a rather strictly *logical* meaning, in as much as the predicate of a judgment is considered to be something accidental to the subject, provided the predicate is *not the definition* of the subject. An affirmative judgment expresses an identity between subject and predicate. But this may be deceptive (and therein lies the danger of fallacy), because this identity will not be a complete identity in every respect, except when the predicate is the definition of the subject or vice versa. If the definition is used, the subject and predicate can be *interchanged*, as 'Man is a rational animal' and 'A rational animal is man'; in this case, whatever is true of the one is also true of the other. Ordinarily, however, the identity of 'S is P' refers to the individual who is the 'subject' and to whom the attribute of the 'predicate' is applied; but the comprehension of 'subject' and 'predicate' (except in the case of a definition) will be only partly identified. Thus, in the judgment 'Man is an animal,' the identity between the two is not complete, because the ideas

are not interchangeable; hence, while it is true that 'Every man is an animal,' it is not true that 'Every animal is a man.' Sometimes the predicate is synonymous with the subject, as when I say that 'A lance is a spear'; sometimes, the ideas of subject and predicate are totally different (though both are found together in this individual), as in the statement that 'This dog is black'; sometimes subject and predicate are partly the same and partly different, e.g., 'Man is an animal'; and sometimes they are identical in all respects, as in a definition, e.g., 'Man is a rational animal.' Except, then, in the case of synonymous ideas or definitions, one cannot consider the subject and predicate as completely identified, so that, what is applicable to the one, must also be applicable to the other, unless the statement is made precisely of that element or those *elements which they have in common*; to act otherwise would mean to be guilty of the 'fallacy of accident.'

Aristotle gives the following example to illustrate the point. The sophist asks: 'Do you know this man with his face muffled?' 'No.' 'Do you know Coriscus?' 'Yes.' 'But the man with his face muffled is Coriscus; you have both asserted and denied that you know Coriscus.' Of course, it is true enough that 'Coriscus' and 'this man with his face muffled' are identical as far as the *individual* is concerned; but 'to have his face muffled' is only accidental to 'Coriscus,' and one can know the one without knowing the other. Here is another instance: 'Man has intelligence; but intelligence is a Divine Attribute; ergo, man has a Divine Attribute.' It is correct that 'man has intelligence'; but the two ideas ('man' and 'intelligence') are not identical to such an extent that

everything which can be affirmed of 'intelligence' must also apply to 'man.' Again: 'Animal is a genus; man is an animal; ergo, man is a genus. Other logicians interpret the Fallacy of Accident more according to the meaning of 'accident' in the *real order* and place the fallacy in the confusion of the accidental and essential qualities of an object. For instance: 'White is a color; this man is white; ergo, this man is a color.' 'All bovines have two horns; this calf has no horns; ergo, it is no bovine.' 'Men and apes are morphologically alike; ergo, they are substantially the same. August Forel, in *Der Hypnotismus* (1911, p. 8), is guilty of this fallacy when he writes: "The anatomy, physiology and pathology of human and animal brains have brought forth the incontestable proof that the characters of the mind depend on the quality, quantity and integrity of the living brain, and are therefore identical with it. A living brain without a mind can no more exist than can a mind without a brain, and every normal or pathological change of the activity of the mind corresponds to a normal or pathological change of the activity of the neurokymes of the brain, i.e., of its nerve elements. What we recognize introspectively in our consciousness are synthetized activities of the brain. We can therefore accept the theory of the identity regarding the relations of pure psychology (introspection) to the physiology of the brain (the observation of the activity of the brain from without) as long as the facts are consistent." From the accidental and extrinsic dependence of man's mind on his brain, Forel argues to the identity of the two, so that what is true of the one is necessarily true of the other. How fallacious this line of reasoning is, can be seen by

employing the same argument to show that, since 'man's life depends on the quality, quantity and integrity of the living lungs and liver, it is therefore identical with them.'

ONE OF THE MOST DANGEROUS FALLACIES IS THE *FALLACY OF Absolute and Qualified Statements*. It consists in arguing from a statement which is *generally true* (absolute statement, *dictum simpliciter*) to a *specific case*; or from a statement which is true in a *special instance* (qualified statement, *dictum secundum quid*) to the *general class*. The general statement here is a moral universal which is true in a widely accepted sense, but admits of exceptions. A moral universal is valid under ordinary and normal conditions and circumstances, so that one is justified in making a general rule, with the understanding, however, that there may be *limitations to its application*. The fallacy lurks in the exceptions to such a rule. Thus, as a general rule, it is legitimate to state that 'Parents love their children (i.e., ordinarily speaking)'; 'it is wrong to kill a person (i.e., without sufficient reason)'; 'property rights must be respected (i.e., except in the case of necessity)'; 'liquor is harmful (i.e., in many instances)'; 'man is mortal (i.e., in as far as he is a compound of body and soul)'; 'human beings can hear and see (i.e., if they are normal)'; 'children must obey their parents (i.e., as a rule)'; 'the Germans are industrious,' 'the French are vivacious,' 'the Italians are artistic,' 'the Americans are inventive,' 'the Indians are stoical,' 'the Japanese are aggressive,' 'the English are good colonizers (i.e., as a class with national traits).' Each of

these statements is true, but with a qualifying limitation; the limitation is not mentioned, but it is understood and must be taken into account. To argue, then, from an absolute to a qualified statement (*a dicto simpliciter ad dictum secundum quid*) or from a qualified to an absolute statement (*a dicto secundum quid ad dictum simpliciter*) would be fallacious.

We cannot legitimately conclude from what is true or good under certain circumstances of time, place, or condition to the truth or goodness of this same thing under all circumstances; that would involve the fallacy of jumping from a qualified to an absolute statement. For instance, because a representative form of government is good for Americans, we are not entitled to infer that it would be good for the Filipinos or for other nations in general. Because some capitalists are unjust to labor, that does not mean that capitalism as such is unjust. Because some people get drunk, is no reason for forcing prohibition on an entire nation. Because Galileo was restrained, is no argument that the Church is against science. Because a man is the head of a large industry or is a great scientist, that of itself makes him no authority in matters of philosophy, religion, or statecraft. To judge in this fashion is to commit the fallacy of passing from a qualified statement to an absolute statement. All snap-judgments, where we make hasty generalizations from a limited experience, belong to this class.

The fallacy which concludes from a statement of general truth to a particular instance, irrespective of limiting and qualifying conditions and circumstances, is an equally

dangerous procedure. It is the fallacy of passing *a dicto simpliciter ad dictum secundum quid*, from an absolute to a qualified statement. 'It is not permissible to kill one's fellow man'; but on that account one cannot condemn a man for killing another in self-defense or in a just war. 'It is wrong to indulge in narcotics'; but we must not conclude that it is wrong for a physician to prescribe a narcotic for a patient whose physical welfare requires the drug. 'The Church is holy'; but this does not demand that there be no sinners in the Church. 'Punishment for crime is necessary'; but that does not condone mob-rule and lynching. 'Picketing during strikes and lockouts are just measures of self-protection on the part of labor unions'; but that does not justify sabotage and violence. To extend any such general principle to every special case without exception, ignoring the individual character of the case, means to be guilty of this fallacy. Narrow-minded people, bigots, and propagandists usually fall into this error.

IGNORING THE ISSUE IS ANOTHER ABUNDANT SOURCE OF fallacies. Logicians, following Aristotle, call it *ignoratio elenchi*, 'ignoring the disproof' (namely, of the adversary); it received this name because of the fact that it is usually committed by not actually disproving an opponent's conclusion. It is also called 'mistaking the question,' 'irrelevant conclusion,' 'arguing beside the point,' 'evading the issue.' The meaning of all these expressions is the same: One either proves what is not in question to be proved, or does not prove what is supposed to be proved, or disproves

what has not been asserted; one either proves too much, or not enough, or something beside the question. In other words, one does not prove (or disprove) the point at issue.

Participants in a political campaign, in a religious controversy, in a scientific debate, in the legal proceedings of a criminal case, frequently fall into this error. Personal abuse, instead of reasons, never proves a fact or establishes a principle or refutes an argument. Those who deny the immortality of the soul on the grounds that 'No dead man ever came back' are arguing beside the point; so, too, are they who claim that a man could not have committed a certain crime, because, 'He went to church every Sunday.' It is the same sort of fallacy to judge the worth of a religion by the material progress of the nations who profess it. To decry the political ability of a man by stating that 'He was born on the farm and can therefore know nothing of the big questions of government,' is to evade the issue. To propagandize the people against a presidential candidate on the grounds of his religious affiliation, is a form of mistaking the question.

This fallacy appears in numerous guises. It is called an *appeal to the people* (*argumentum ad populum*), when no solid reasons are advanced for a certain principle or measure, but merely an appeal to the prejudices and passions of the populace. This is the usual method of the soap-box orator of the communistic type, who works up the feelings of his hearers by a harrowing picture of poverty-stricken workers and starving women and children. He attacks the abuses of wealth and capitalistic oppression in vitriolic language, but he does not prove thereby that

communism is an economically sound system. The same form of argument is used by those who inflame the religious prejudices of well-meaning Protestants by claiming that the election of a Catholic president would make the whole country subject to a foreign potentate.

The *appeal to might* (*argumentum ad baculum*) is the threat of dire consequences to those who will not follow a certain course or dare to oppose a certain policy. This play upon fear is an unworthy attempt to substitute penal measures for arguments which are either weak or entirely lacking. It is not wrong for parents to threaten punishment for disobedience. But if a powerful industry threatens reduction in wages or loss of employment to its workers, if they form a labor union, then that is an 'appeal to might.'

In the *appeal to shame or modesty* (*argumentum ad verecundiam*) one does not argue a question on its intrinsic merits, but strives to convince a person by pointing out the *dignity* of those who adhere to a certain view. There is, naturally, a legitimate place for the citation of authorities in a question, provided their arguments are given, in order to support one's own view; but a mere array of prominent names should not be used to cow an opponent. The opinion of men who are experts in their own line deserves respect and recognition *in their particular field*, but the greatness of their fame should not be used as an argument regarding questions *outside their field*; that would be a fallacy. Edison was a genius in electricity; but his views on the nature of the soul or the hereafter carry no weight, because these problems lie outside the province of his specialty.

The *appeal to pity* (*argumentum ad misericordiam*), as the name indicates, leaves reasons aside and pleads for *mercy*. When a lawyer in a criminal case plays on the heart-strings of the jury on the grounds of the youth of the criminal or the pain that will be inflicted on the parents, instead of proving the innocence of the accused, he is arguing beside the point and is guilty of this fallacy; this is particularly the case, when the accused is not a first offender, but a hardened criminal.

In the *appeal to ignorance* (*argumentum ad ignorantiam*) one relies on the *lack of knowledge* on the part of the hearers to hinder them from seeing through the speciousness of one's arguments. Statistics are thus often used and abused by orators) knowing that the audience is not acquainted with the facts or with the proper interpretation of the figures. Speaking to an uneducated mass meeting, the speaker will frequently sway his audience with the fire of his enthusiasm and the grandiloquence of his language, convinced that the play of his words will do more than any amount of cogent reasoning.

The *appeal to the individual* (*argumentum ad hominem*) shows that the character or the previous views of an opponent are such that he is *not the proper person* to uphold the statements he is making. When a Democrat argues that his Republican opponent was himself formerly a Democrat, then he is weakening the authority of his opponent; in as much, however, as the Democrat is not disproving his opponent's arguments as such, he is guilty of this fallacy, because it is not a question of personality but of

principle. When, however, an attorney shows to the court that the witness has a criminal record, he has the perfect right to bring this fact to the attention of the court, because the criminality of the witness has a direct bearing on his credibility. A common form of this fallacy is to heap abuse or ridicule upon an opponent, instead of meeting his arguments with counter-arguments.

From all this it will readily be seen that the *ignoratio elenchi* or 'ignoring the issue' is a dangerous weapon of sophistic reasoning, one whose prevalence and insidious use works incalculable harm in the minds of men.

ANOTHER IMPORTANT FALLACY IS THAT OF *BEGGING THE QUESTION* (*petitia principii*). It is an argumentation in which the very *conclusion* (question) to be proved is, in some form or other, *assumed to be true*; or, when the conclusion is proved by a principle whose truth *depends on the truth of the conclusion itself*.

In the first type some *synonymous* term is usually employed to cover the fallacy. Such would be the case, if we explained 'heart failure' by saying it was due to a 'paralysis of the cardiac contractile muscles'; or, that morphine 'induces sleep' because it has a 'soporific effect'; or, that Roosevelt's method of ending the depression is a 'dictatorship' because he is a 'virtual Mussolini.' This last instance ('Roosevelt-Mussolini') is also a case of *question-begging epithet*, which consists in using some phrase or term to explain or prove something by implication, although the question to be explained or proved is *presupposed* in

the epithet itself; the epithet is taken as proof while it needs proof itself. Such would be the reasoning of a criminal who contends that he was justified in killing a policeman, because he acted in self-defense' against the policeman. Whoever contends that all wars are nothing but 'uncivilized slaughter,' because every war is 'an atrocious piece of barbarity,' is guilty of this fallacy; he presupposes the very thing he is to prove.

The second type is committed when some *principle*, wider than the conclusion, is used as proof for the conclusion and its *truth assumed without independent proof*. If the conclusion needs proving, being an instance involved in this wider principle, then this wider principle needs proving all the more; to assume the truth of this principle is then a 'begging of the principle or question.' When materialists attempt to prove that the world was not created, by saying that 'matter is eternal, and therefore the world is eternal,' they presuppose the truth of the principle that 'matter is eternal' and thereby beg the question, because this principle is the very thing they ought to prove. To assert that 'communism is the best form of government, because it alone takes care of the interests of the common people,' is to be guilty of the same fallacy. Galileo ascribed the following argument to Aristotle, wherein the major premise begs the question: 'The nature of heavy things is to tend *toward the center of the universe*, and of light things to fly from it; experience proves that heavy things tend toward the center of the *earth*, and that light things fly from it; therefore the center of the earth is the center of the universe.'

When a conclusion is proved by a principle used as a premise in an argument, and later on this same principle is proved by this conclusion used as a premise in a different argument, we have a vicious circle: In the one case the 'first' is proved by the 'second,' and later on this 'second' is proved by the 'first.' It would be a 'vicious circle,' for instance, to prove the 'freedom of the will' from the fact of 'personal responsibility,' and then later on prove the fact of 'personal responsibility' from the principle of the 'freedom of the will.' So, too, one would be guilty of 'arguing in a circle,' if one attempted to prove the 'immortality' of the soul from its 'spirituality,' and then at a later stage attempted to prove its 'spirituality' from the fact of its 'immortality.'

THE *FALLACY OF THE CONSEQUENT* IS COMMITTED, WHEN WE USE a conditional syllogism and argue from the falsity of the antecedent to the falsity of the consequent, or from the truth of the consequent to the truth of the antecedent. The rules of a legitimate argumentation, based on a conditional statement, are, as we have seen when treating of this type of syllogism, the reverse of this fallacy. 'If it is A, then it is B; it is A; ergo, it is B.' 'If it is A, then it is B; it is not B; ergo, it is not A.' It is only when positing A, that we are allowed to posit B; and it is only when sublating B, that we are allowed to sublate A. To turn this inferential process around is to commit the Fallacy of the Consequent.

This fallacy is of daily occurrence. Here are some examples: 'If he is lazy, he will flunk; he flunked; ergo, he

was lazy.' This does not necessarily follow; he may have been sick, thereby missing many classes, Or the other way: 'He was not lazy; ergo, he did not flunk.' He may have very weak talents, so that, even though he studied well, he was not able to pass. The same is true of the following argument: 'If the Soviet is a good form of government, it will survive; it survives; ergo, it is a good form of government.' Here one argues from the truth of the consequent to the truth of the antecedent, and that is fallacious reasoning; the Soviet might survive, not because it is a good form of government, but because of the brutal force with which the officials of the Soviet suppress every attempt on the part of the people to put a sane government in its place. Pseudo-scientists (and even real scientists) frequently are guilty of this fallacy, when they argue in the following fashion regarding evolution: 'If evolution took place, there must be a gradual succession of living forms, ranging from the most primitive to the most specialized; there exists such a gradual succession of living forms; ergo, evolution took place.' One simply cannot make a legitimate inference from the truth of the consequent to the truth of the antecedent, *unless there is no other alternative*; in this case, however, there is still creation as an alternative. Such a conclusion may be true, but it need not be.

IN THE *FALLACY OF FALSE CAUSE* WE ASSIGN A WRONG CAUSE TO A certain effect. Superstitions are based on this fallacy. An accident happens on a Friday; ergo, it was the 'unlucky' day which caused it. An aviator carries a 'luck piece' with him

on his *flight*; the plane plunges to the earth, but he is not killed; it was his 'luck piece' that saved him. A man's business fails, because he went golfing too much and did not give proper attention to his affairs; he blames 'the crooked methods' of his competitors for his bankruptcy.

To this type we must also refer the fallacy of '*after this, ergo on account of this*' (*post hoc, ergo propter hoc*). Simply because one event follows another event is no evidence that the former is caused by the latter. Here are some typical arguments of this kind. 'Man follows the ape in the succession of primates; ergo, man is descended from the ape.' 'The Roman Empire declined and fell after the appearance of Christianity; ergo, Christianity is the cause of the decline and fall of the Roman Empire.' 'The Catholic countries have declined in their temporal progress and prosperity, since they were converted to the Catholic Church; ergo, the Catholic Church is responsible for their lack of progress and prosperity.' Because malarial fever is prevalent in swampy regions, it was commonly thought that the fever was due to the poisonous vapors emanating from the swamps.

The Fallacy of False Cause is of frequent occurrence in the *inductive sciences*. The danger there is indeed very great. In consequence of the uninterrupted flux and intermingling of concrete causes and effects many factors may be overlooked or misinterpreted in explaining a phenomenon. The purpose of experiments is to isolate these factors and simplify their study. This is done by shunting out the unessential and irrelevant elements, so as to retain only those which actually contribute to the production of a

particular effect. Experimentation is, therefore, a *selective* process, depending for its effectiveness and validity on the knowledge and mental acumen of the individual scientist. But therein also lies its danger. The investigator is always guided in his experiments by some *hypothesis* of cause or law, and his desire to establish this hypothesis may lead him astray. He may overlook some very important factors and over-stress others; he may unconsciously retain only such elements as favor his hypothesis, excluding those which would tend to disprove or modify it. His interpretation of facts may be faulty. As a result he may designate something as a cause which is only a concomitant circumstance or condition. His generalizations may be too hasty, so that they amount to nothing more than sweeping statements.' This is especially the case when, in his anxiety to establish a law, he does not take the time to examine enough instances, being content with a very incomplete induction. Oftentimes this lack of thoroughness is due to the lack of the necessary means of observation. Thus, Dalton's Atomic Theory, which considered the atom as the ultimate indivisible 'element in nature, was universally accepted as true; now, however, improved methods of observations have quite definitely established the fact that the breaking up of the atom, or 'atomic disintegration,' goes on continually. So, too, Einstein's Theory of Relativity bids fair to revolutionize many accepted generalizations of astrophysical phenomena. Science is not at all so sure of many of its so-called 'laws' as some popularizers would have us believe. Nature is very deep and mysterious in its operations and contains many unsounded depths. The pitfall of False 'Cause

is always near at hand, ready to swallow the unwary and the presumptuous.

Truth and fallacy form a strange mixture in our minds. Truth comes piecemeal to us, the result of observation, study, experimentation, endless analysis, and synthesis. Truth lies concealed in the husks of concrete sense-data, in the multiplicity of physical phenomena and mental reactions, and slowly, laboriously, patiently the mind must pare away all extraneous matter by a process of abstraction and generalization, so as to grasp the kernel within. That man's knowledge will frequently consist of only part of the real truth, or that errors will cling to the pure kernel of the truth acquired, is but a natural consequence of the limited power of the mind and the vastness of the field from which truth must be drawn. But it is the glory of man to be endowed with reason. It makes him akin to God. It lifts him above the brute things of a physical world and enables him to follow the trail of the Divine Intellect fashioning the universe according to plan and measure.

It is the high privilege of man's mind to seek for truth and knowledge, but it is a difficult task. Ideas and judgments and argumentations, induction and deduction — these are the paths along which the intellect must travel in its search for truth. There are pitfalls of error along the route; but logic, the science of correct thinking, will guide our steps, so that we can reach the sublime heights of Truth.

SUMMARY OF CHAPTER XXI

Formal errors are violations of the rules which govern the fundamental forms of reasoning. *Material errors* are errors of facts or faulty use of ideas and words. If these latter have a *deceptive resemblance* to truth and are used with a purpose of misleading, they are sophisms; but if their use is unintentional, they are *fallacies*. There are *Fallacies in Language* and also *Fallacies in Matter*.

1. The following are Fallacies in *Language*:

Equivocation, using a word in different meanings. *Amphiboly*, using phrases or entire sentences ambiguously. *Composition*, taking conjointly what should be taken separately. *Division*, taking separately what should be taken conjointly. *Accent* or *Prosody*, ambiguity due to false accent or false emphasis. *Figures of Speech*, when a conclusion of identity or similarity of meaning is drawn between one diction and another, due to their similarity of construction.

2. The following are Fallacies in *Matter*:

Accident, the confusion of accidental and essential characteristics of a thing. *Absolute and Qualified Statements*, arguing from a generally true statement to a specific case, or from a special case to the general class. *Ignoring the Issue*, proving what is not to be proved, not proving what is to be proved, disproving what has not been asserted. *Begging the Question*, assuming as true the very thing to be proved. *Consequent*, arguing from the falsity of the antecedent to the falsity of the consequent, or from the

truth of the consequent to the truth of the antecedent.
False Cause, assigning a wrong cause to a certain effect.

GLOSSARY

AMPHIBOLY (Gr., *amphibolos*, equivocal). The Fallacy of Amphiboly consists in the ambiguous use of a phrase or of a complete sentence.

ANALOGOUS (Gr., *analogia*, ratio, proportion). An analogous term is one which applies to unlike, but related, things.

ANALOGY. That reasoning process whereby the mind concludes from the known characteristics of one thing or group of things to the unknown characteristics of another thing or group of things because of a recognized resemblance existing between them.

ANALYSIS (Gr., *ana*, backwards, and *lyein*, to loosen, resolve). The scientific method which passes from the concrete to the abstract, from the complex to the simple, from the particular to the universal, from the application of a principle to the principle itself, from the phenomena to the underlying general law, from the effects to the cause. Synonym: *A posteriori* method.

ANALYTIC PROPOSITION. One in which either the predicate is contained in the comprehension of the subject,

or the subject is contained in the comprehension of the predicate. Synonyms: Necessary, essential, *a priori*.

APPLICATION. With reference to ideas, same as extension. See Extension.

A POSTERIORI (Lat., *posterior*, after). Argument drawn from effects, consequents, or facts.

A PRIORI (Lat., *prior*, before). Argument drawn from definitions formed or principles assumed, or which infers effects from causes previously known.

ARGUMENTATION. The verbal expression of a mediate inference.

ASSERTORIC PROPOSITION (Lat., *asserere*, to maintain, assert). Same as categorical proposition.

AVERAGE. The mean proportion, medial sum or quantity, made out of unequal sums or quantities.

AVERAGE, ARITHMETICAL. The sum of the particular items divided by their number.

AVERAGE, WEIGHTED. An average whose particular items have been multiplied by certain weights before their addition, and this sum is then divided by the sum of the weights instead of by the number of items.

BEGGING THE QUESTION. It is a fallacy in which the very conclusion (question) to be proved is, in some form or other, assumed to be true; or, when the conclusion is proved by a principle whose truth depends on the truth of the conclusion itself. Synonym: *Petitio principii*.

CATEGORICAL PROPOSITION. One that makes a direct assertion of agreement or disagreement between subject

and predicate.

CATEGORICAL SYLLOGISM. A syllogism whose premises are categorical propositions.

CATEGORY (Gr., *kategorein*, accuse, predicate). A supreme and ultimate class of direct universals. Synonym: *Predicament*.

CAUSAL DEFINITION. The explanation of a thing by means of its efficient or final causes.

CAUSAL PROPOSITION. One that combines two statements in such a way that the one is given as the reason or cause of the other.

CAUSALITY, Principle of. It is the principle which states that 'whatever happens (occurs, changes, begins to be) has a cause'; or, 'whatever is contingent (i.e., is not the self-sufficient reason of its own existence and being) has a cause for its existence and being'; or, 'every effect has a cause.'

CAUSE. Anything that contributes in some positive manner toward the production of another thing in its existence and being.

CIRCULAR DEFINITION. One in which a first idea is defined by a second, and later the second is defined by the first.

CLEAR IDEA. One which represents an object in such a way that we can distinguish it from any other object.

COLLECTIVE IDEA. One that applies to all the individuals as a class, but not to the single members of the class.

COMPARATIVE PROPOSITION. One that compares the relation between a subject and predicate with the same relation between another subject and predicate, and

expresses the degree of this relationship as being either less or equal or greater.

COMPATIBLE IDEAS. Ideas in which the attributes of the comprehension of both can be united into another (third) idea.

COMPLEX PROPOSITION. It is a composite sentence in which both the subject and the predicate or either one is a complex term.

COMPLEX TERM. See Compound term.

COMPOSITE PROPOSITION. One in which a qualification or composition enters into the subject or predicate or copula of a simple sentence.

COMPOSITION, Fallacy of. A fallacy in which something is taken conjointly which should, be taken separately.

COMPOUND TERM. One that consists of more than one word.

COMPREHENSION. The comprehension of an idea is the sum total of all the attributes or thought-elements which constitute the idea in its representation of a thing. Synonyms: Implication; connotation; intent; intension.

CONCEPT. See Idea.

CONCRETE IDEAS. Those which express a nature or determining attribute as inherent in a subject.

CONDITION. Something which enables a cause to produce its effect, without actually contributing toward the production itself.

CONDITIONAL PROPOSITION. One that expresses a relation in virtue of which one proposition necessarily flows from the other.

CONDITIONAL SYLLOGISM. A syllogism which contains a conditional proposition as the major premise.

CONFUSED IDEA. An idea which, though it enables the intellect to distinguish the represented object from other objects, does not enable it to enumerate the various attributes which make up the comprehension of the object.

CONJUNCTIVE PROPOSITION. A statement asserting that two alternatives are not or cannot be true simultaneously.

CONNEX IDEAS. Ideas which necessarily include or exclude each other.

CONNEX PROPOSITION. Same as conditional proposition.

CONNOTATION. See Comprehension.

CONSEQUENT, Fallacy of. An argument in which we use a conditional syllogism and argue from the falsity of the antecedent to the falsity of the consequent, or from the truth of the consequent to the truth of the antecedent.

CONTRADICTION, Principle of. The principle which states that 'it is impossible for the same thing both to be and not to be at the same time.'

CONTRADICTION, Relation of. It is the logical opposition existing between a universal affirmative and a particular negative proposition, and between a universal negative and a particular affirmative proposition.

CONTRADICTORY IDEAS. They are ideas of which the one simply denies the comprehension of the other.

CONTRAPOSITION. A form of eduction in which the subject of the inferred proposition is the contradictory of the predicate of the original proposition.

CONTRARIETY. A form of logical opposition existing between a universal affirmative and a universal negative.

CONTRARY IDEAS. Those which represent the two extremes among object of a series belonging to the same class.

CONVERSION. A form of eduction in which the inferred judgment takes the subject of the original proposition for its predicate, and the predicate of the original proposition for its subject.

COVERTLY MULTIPLE PROPOSITIONS. They are propositions which have the appearance of single propositions, although they are really multiple.

DEDUCTION (Lat., *deducere*, to draw from). It is the process of reasoning in which we conclude from the general law or principle to a particular instance falling under the general law or principle.

DEFINITION (Lat., *definire*, to set the limits). It is a statement which explains what a thing is.

DENOTATION. See Extension.

DESCRIPTIVE DEFINITION. A statement which explains what a thing is in itself by enumerating the positive, but nonessential, elements of its nature.

DESITIVE PROPOSITION (Lat., *desistere*, to cease). A statement including a declaration of time when something ends.

DETERMINING CAUSE. An active, originative condition enabling a cause to act.

DICTUM DE OMNI ET NULLO. An axiom underlying the syllogism which states: 'What is affirmed of a logical whole

may be affirmed of a logical part of that whole; and what is denied of a logical whole may be denied of a logical part of that whole.'

DIFFERENTIA (Lat., for difference). A universal idea or predicable which expresses a part of the essence of its subject, that part which distinguishes one species from another under the same genus.

DILEMMA (Gr., *dis*, double, and lemma, gain, assumption). It is an argument in which the major premise consists of a disjunctive proposition and the minor premise consists of conditional propositions, each of which takes one member of the disjunction and from it draws a conclusion detrimental to the adversary.

DIRECT UNIVERSAL. It is a universal idea which expresses the nature or essence of a thing as it is in itself, without relation to other things or ideas. Synonyms: Real; immediate; metaphysical; of the first intention.

DISCRETIVE PROPOSITION. See Adversative.

DISJUNCTIVE PROPOSITION (Lat., *disjungere*, to separate). An 'either — or' statement, indicating that the implied judgments cannot be true together nor false together, but one must be true and the others (or other) false.

DISJUNCTIVE SYLLOGISM. A syllogism whose major or minor premise consists of a disjunctive proposition.

DISPARATE (Lat., *dispar*, unequal, unlike). Ideas are disparate when they neither necessarily include nor necessarily exclude each other.

DISTINCT IDEAS. Ideas which not only enable the intellect to distinguish the represented object from other

objects, but also enable the intellect to enumerate the various attributes which make up the comprehension of the object.

DISTINCTIVE DEFINITION. One which explains a thing by its properties.

DISTRIBUTIVE SUPPOSITION (Lat., *distribuere*, to give or divide). The use of a term so that it applies to all the individuals taken singly and all together as a class; the use of a term as a universal.

DIVERSE IDEAS (Lat., *diversus*, different). Ideas whose comprehension is different from each other. DIVISION. That mental operation which resolves a whole into its parts.

DIVISION, Fallacy of. The fallacy in which that is taken separately which should be taken conjointly.

EDUCTION (Lat., *educere*, to draw forth, extract). It is a process of immediate inference whereby, from any proposition taken as true, we derive others implied in it, though differing from the first in subject, predicate, or both.

EFFICIENT CAUSE. It is the agent which actively produces a thing or a new state in a thing.

ENTHYMEME (Gr., *en*, in, and *thymos*, soul, mind). An abridged syllogism, in which one of the premises or the conclusion is omitted.

EPICHIREME (Gr., *epi*, upon, and *cheir*, hand). A syllogism in which the proof is conjoined to one of the premises.

EQUIPOLLENCE (Lat., *aequus*, equal, and *pollere*, to have value). See Obversion.

EQUIVOCAL TERM (Lat., *aequus*, like, *vox*, voice, sound). A term that is used in entirely different meanings.

EQUIVOCATION, Fallacy of. A fallacy which consists in using a word in different meanings.

ESSENTIAL (Lat., *esse*, being). Belonging to the essence or nature of a thing.

ESSENTIAL DEFINITION. A statement which explains the essence or nature of a thing. Synonym: *Quidditative*.

ESSENTIAL PROPOSITION. See Analytic proposition.

EVIDENCE, CIRCUMSTANTIAL. Those relevant circumstances or facts which enable us to draw legitimate inferences to some principal fact, which fact then explains the existence and presence of these relevant circumstances or facts.

EXCEPTIVE (Lat., *ex*, out, 'from, and *cape re*, to take). An exceptive proposition is one which contains a particle of speech like 'except' or 'save,' to indicate that a portion of the extension of the predicate does not apply to the subject, or Vice versa.

EXCLUDED MIDDLE, Principle of. A principle which states that 'a thing either is or is not,' 'any attribute must be either affirmed or denied of any given subject,' 'two contradictories cannot be false together,' 'one of two contradictories must be true,' 'between affirmation and denial there is no middle course,' 'between two contradictories a middle is excluded.'

EXCLUSIVE PROPOSITION. A statement which indicates the exclusion of any other predicate from this subject or any other subject from this predicate.

EXISTENTIAL IMPORT. The implication of existence contained in a judgment.

EXPERIMENT. The observation of phenomena under selective and controlled conditions.

EXTENSION. The sum total of all the individuals and groups to which any idea can be applied. Synonyms: Denotation, application.

EXTRA-SYLOGISTIC INFERENCE. Certain forms of mediate inference which follow the general line of thought characteristic of the syllogistic figures, but do not seem to conform to the basic idea of these figures.

FALLACIES IN LANGUAGE. These are fallacies which rest upon the lack of preciseness in the words used to express thoughts.

FALLACIES IN THE MATTER. These are fallacies which are the result of confusion in the matter or things stated.

FALLACY (Lat., *fallere*, to deceive). An error or argumentation, based on the use of words or ideas which have a deceptive resemblance to truth and thereby lead to avoidable false conclusions.

FALSE CAUSE, Fallacy of. A fallacy which assigns a wrong cause to a certain effect.

FIGURE, Syllogistic. The disposition or arrangement of the middle term with respect to the major and minor terms in the premises of a syllogism.

FIGURES OF SPEECH, Fallacy of. A fallacy in which a conclusion of identity or similarity in meaning is drawn between one diction and another, due to their similarity of construction.

FINAL CAUSE (Lat., *finis*, purpose, end). The purpose or aim which induces the efficient cause to act and directs this action throughout its operation.

FIRST INTENTION, Universal of the. See Direct universal.

Fixed TERMS. Those whose signification remains the same.

FORMAL CAUSE (Lat., *form a*, form, mold, pattern, model). The inner, active part of the produced thing which is the determining element of the new (caused) reality in the produced thing.

FORMAL SUPPOSITION. The use of a term according to its signification.

GENETIC DEFINITION (Gr., *gennao*, to beget). A statement which explains a thing by its process of origin or production.

GENUS (Gr., *genos*, race, kind). A predicable or universal idea which expresses a part of the essence of its subject, that part which the subject has in common with other species in this same class.

HABITUS (Lat., *habitus*, from *habere*, to have, hold). A category or universal idea expressing clothing, equipment, physical adjuncts; or a state, as expressed by the reflexive verb.

HYPOTHESIS (Gr., *hypotith emi*, to place under; a foundation, assumption). The provisional explanation of a phenomenon, based on probable arguments, until verified (or disproved) by subsequent events.

HYPOTHESIS OF CAUSE. A hypothesis which is used to establish the cause or causes which contribute toward the

production of a phenomenon.

HYPOTHESIS OF LAW. A hypothesis which is used in an attempt to explain the manner in which the causes of a phenomenon operate.

HYPOTHETICAL PROPOSITION. One that expresses the dependence of one affirmation or denial on another affirmation or denial. Sometimes it is applied to the conditional proposition alone.

HYPOTHETICAL SYLLOGISM. A syllogism in which a hypothetical proposition occurs as the major premise.

IDEA (Gr., *eidos*, that which is seen, image). The intellectual image or representation of a thing. Synonyms: Concept; notion.

IDENTICAL IDEAS (Lat., *idem*, same, and *ens*, being). Those ideas whose comprehension is the same.

IDENTITY, Principle of. The principle which states that 'whatever is, is,' 'everything is what it is,' 'a thing is what it is.'

IGNORATIO ELENCHI (Lat., *ignorare*, to lack knowledge; Gr., *elegchos*, disproof, refutation). A fallacy in which one either proves what is not in question to be proved, or does not prove what is supposed to be proved, or disproves what has not been asserted.

IGNORING THE ISSUE, Fallacy of. Same as *Ignoratio Elenchi*.

ILLICIT MAJOR. An illicit argumentation in which the major term of a syllogism is taken wider in the conclusion than in the premise.

ILLICIT MINOR. An illicit argumentation in which the minor term of a syllogism is taken wider in the conclusion than in the premise.

ILLICIT PROCESS. An illicit argumentation in which either the major or the minor term is given wider meaning in the conclusion than in the premises.

IMMEDIATE IN'FERENCE (Lat., *in*, in, and *ferre*, to bear, produce). The method of concluding from the truth or falsity of one statement to the truth or falsity of another statement without the aid of another judgment.

IMMEDIATE UNIVERSAL. See Direct universal.

IMPLICATION. See Comprehension.

INCEPTIVE PROPOSITION (Lat., *incipere*, to begin). One that includes a declaration of time when something begins.

INCOMPATIBLE IDEAS. When the comprehension of one idea excludes the attributes of the other.

INCOMPLEX TERMS. Simple terms.

INDUCTION (Lat., *inducere*, to lead into). It is that process of reasoning in which we conclude from the individual cases to the existence of general laws or principles.

INTENSION. See Comprehension.

INTENT. See Comprehension.

INTUITIVE IDEAS (Lat., *intueri*, to see, behold). Those which are formed as the result of direct perception of things. Synonym: Immediate ideas.

INVERSION (Lat., *in*, in, and *vertere*, to turn). A method of eduction in which the mind, by means of obversion and conversion, finally arrives at a judgment in which the subject is the contradictory of the original subject.

JUDGMENT (Lat., *judicare*, to judge, pass a verdict). A judgment is an act of the mind pronouncing the agreement or disagreement of ideas among themselves.

LOGIC (Gr., *logos*, word, discourse). Logic is the science of those principles, laws, and methods which the mind of man in its thinking must follow for the accurate and secure attainment of truth.

LOGICAL DIVISION. It is the resolving of a universal idea into the members which constitute its extension.

LOGICAL OPPOSITION. The relation which exists between propositions having the same subject and the same predicate.

LOGICAL UNIVERSAL. It is a universal idea which expresses a nature common to many, precisely in so far as it is applicable to many. Synonyms: Reflex universal, universal of second intention.

MATERIAL CAUSE. It is that inner, passive part of the produced being which is determined and changed by the action of the efficient cause.

MATERIAL SUPPOSITION. The use of a word merely as a word, without regard to its inherent meaning.

MEDIAN. The middle quantity or item in a series arranged according to magnitude.

MEDIATE IDEAS. See Abstractive.

MEDIATE INFERENCE. The process by which, from certain truths already known, the mind passes to another truth distinct from these but necessarily following from them.

METAPHYSICAL UNIVERSAL (Gr., *meta*, beyond, and *physis*, nature). See Direct universal.

METHOD (Gr., *methodos*, system). The proper arrangement of our mental processes in the discovery and proof of truth.

MODAL PROPOSITION (Lat., *modus*, manner, qualification). A composite single sentence in which the copula is so modified as to express the manner (mode) in which the predicate belongs to the subject.

MODE. The quantity or item which appears with greatest frequency in a group.

MOODS (MODES), Syllogistic. The arrangement of the premises according to quantity (universality or particularity) and quality (affirmation or negation).

MULTIPLE CATEGORICALS. Propositions which contain two or more categorical sentences in their very construction.

NECESSARY PROPOSITIONS. See Analytic propositions.

NEGATIVE TERMS Those which signify the absence of a thing.

NOMINAL DEFINITION (Lat., *nomen*, name). One that explains what a word means.

NOTION (Lat., *notio*, from *noscere*, to know). Same as Idea.

OBSCURE IDEAS (Lat., *obscurus*, dark). Ideas which represent things in such a manner that we cannot distinguish them clearly from every other object.

OBSERVATION (Lat., *observare*, to behold). The close scrutiny and examination of natural occurrences.

OBVERSION (Lat., *ob*, before, toward, and *vertere*, to turn). A process of eduction in which the inferred judgment, while retaining the original subject, has for its predicate the contradictory of the original predicate. Synonym: Equipollence.

OPPOSITION, Logical. See Logical opposition.

OVERTLY MULTIPLE CATEGORICALS. Categorical propositions which are plainly composed of two or more sentences.

PARTICULAR IDEAS. Universals taken partly and indeterminately.

PASSION (Lat., *pati*, to suffer, bear, endure). As a category it is a universal signifying the reception of an effect from another.

PERSONAL SUPPOSITION. The use of a term to signify both the nature and the bearers of this common nature.

PETITIO PRINCIPLE. See Begging the question.

PHILOSOPHY (Gr, *philein*, to love, and *sophia*, wisdom). Philosophy is the Science of beings in their ultimate reasons, causes, and principles, acquired by the aid of human reason alone.

PLACE. As a category it is a universal idea signifying position in space.

POLYSYLLOGISM (Gr., *polys*, many). An argumentation consisting of two or more syllogisms, logically connected together in such a way that the conclusion of the preceding syllogism becomes the premise of the one following.

POSITIVE IDEAS Those which signify a real, actual thing.

POSTURE A category signifying immanent or intransitive action expressed by an intransitive verb; disposition of parts among themselves, in the sense of 'attitude.'

PREDICABLES (Lat., *predicare*, to announce). The different modes or ways in which a universal can be predicated of its subject.

PREDICAMENTS. Same as Categories.

PRIVATIVE IDEAS (Lat., *private*, to rob, take away). Those where one signifies a perfection and the other denies a perfection in a subject which naturally ought to possess it.

PROBABILITY, OBJECTIVE. That condition or quality of things and facts, when present to the mind, which enables the mind to decide for the truth of a judgment concerning these things and facts, but with the fear of the possibility of error.

PROPERTY. A predicable or universal idea which expresses something which necessarily flows from the essence, though not of the essence itself.

PROPOSITION. A judgment expressed in a sentence.

PROSODY, Fallacy of (Gr., *prosodia*, tone or accent of a syllable). See Accent.

QUALIFIED STATEMENTS, Fallacy of. The fallacy which argues from a statement which is true in a special instance (qualified statement) to the general class.

QUALITY. As a category it is a universal idea signifying a modification of the formal (determining) element in a being.

QUALITY of propositions. The modification of the copula in a sentence, making it either affirmative or negative.

QUANTITY. As a category it is a universal idea signifying a modification of the material (determinable) element in a being; extension, number.

QUANTITY of propositions. The number of individuals to whom the judgment or proposition applies.

QUIDDITATIVE (Lat., *quid*, what). Same as Essential.

REAL DEFINITION. A statement explaining what a thing is in itself.

REAL DIVISION. The resolution of a thing into the natural parts which it has independent of the mind.

REAL SUPPOSITION. The use of a term for a thing in its natural being or existence.

REAL UNIVERSAL. See Direct universal.

REASONING. See Mediate inference.

REDUPLICATIVE PROPOSITION (Lat., *reduplicare*, to double, repeat). One which contains an expression which duplicates the subject or predicate and implies the reason or cause for the connection between subject and predicate.

REFLEX UNIVERSAL (Lat., *re*, back, again, and *flectere*, to bend). See Logical universal.

RELATION (Lat., *relatia*, bearing). AS a category it is a universal idea which signifies the reference or bearing of one being to another.

RELATIVE IDEAS. Two incompatible ideas united in such a way that the one cannot be understood without the other.

RELATIVE PROPOSITION. One which expresses a relationship of time or place between two statements.

SECOND INTENTION, Universal of. See Logical universal.

SIMPLE CATEGORICALS. Propositions which are single and without any qualification or composition.

SIMPLE IDEAS. Those whose comprehension consists of one single attribute or element.

SIMPLE TERMS. One consisting of a single word.

SINGLE CATEGORICALS. Propositions consisting of but a single sentence in their construction, namely one subject, one predicate, and the copula.

SINGULAR IDEAS. Those which represent a single object only.

SOPHISM (Gr., *sophisma*, artifice, quibble). The use of deceptive words and ideas with the purpose of misleading and deceiving.

SORITES (Gr., *soros*, heap, pile). An abridged polysyllogism consisting of three or more premises in such a way that the predicate of the preceding premise becomes the subject of the following premise, the final conclusion being composed of the subject of the first premise and the predicate of the last; or, inversely, one in which the subject of the preceding premise becomes the predicate of the following premise, with the conclusion composed of the subject of the last premise and the predicate of the first premise.

SPECIES (Lat., *species*, form, figure, from *specere*, to see). A predicable or universal idea which expresses the whole essence of a thing.

SPECIFICATIVE PROPOSITION. One which contains an expression which duplicates the subject or predicate and implies the time element or condition of this connection.

STATISTICS. The classification and evaluation of group phenomena by an analysis of data supplied by enumeration and measurement.

SUBALTERNATION. The logical Opposition existing between a universal and particular affirmative, and between a universal and particular negative.

SUBCONTRARIETY. The logical opposition existing between a particular affirmative and a particular negative.

SUBSTANCE (Lat., *sub*, under, and *stare*, to stand). A category or universal idea which expresses a being existing in and for itself, needing no other as a subject in which to exist.

SUFFICIENT REASON, Principle of. The principle which states that 'every thing must have a sufficient reason to be what it is.'

SYLLOGISM (Gr., *sylogismos*, a reckoning all together, a collecting from premises, reasoning). An argumentation in which, from two judgments that contain a common idea and one at least of which is universal, a third judgment, distinct from either of the former, follows with necessity.

SYNTHESIS (Gr., *synthesis*, from *syntithemi*, a putting together, composition). The scientific method in which the mind proceeds from the simple to the complex, from the general to the special, from the universal to the particular, from the necessary to the contingent, from the 'logical whole' to the 'logical part,' from the principle to the applications of the principle, from the general law to the individual cases, from cause to effect.

SYNTHETIC PROPOSITION. One in which neither the subject nor the predicate is contained in the comprehension

of the other. Synonyms: Contingent; accidental; a posteriori.

SUPPOSITION (Lat., *sub*, under, and *ponere*, to put, place). The use of a term or word for the thing which it signifies.

TERM (Lat., *terminus*, limit, boundary). A term is a sensible conventional sign, expressive of an idea.

TESTIMONY. The information or evidence obtained from competent and reliable witnesses.

TIME As a category it is a universal idea which expresses duration of movement.

TRANSCENDENTAL IDEAS (Lat., *trans*, over, beyond, and *scendere*, to rise, climb). Supreme and fundamental ideas which admit of no strict definition because of their extreme simplicity.

UNIFORMITY OF NATURE, Principle of. The principle which states that 'Nature is uniform in its causality'; or, 'the same non-free causes, under the same conditions, will always produce the same results.'

UNIVERSAL IDEAS. They are those ideas which represent some common nature or attribute which can be applied to a class as a whole and to each individual of that class.

UNIVERSAL PROPOSITIONS. Those in which the subject is a universal term used distributively to each and all of the class.

UNIVERSAL TERM. One which expresses a universal idea and can be applied to each individual of a class and to

the class itself.

UNIVOCAL TERM (Lat., *unus*, one, and *vox*, voice, sound). A term used constantly in an identical sense.

VAGUE TERMS. Terms which are subject to shades and degrees of meaning, according to the viewpoint and use of the individual persons.

REALITY AND THE MIND

EPISTEMOLOGY

PREFACE

The validity, or truth-value, of human knowledge is the crucial problem in modern philosophy. It has agitated the minds of philosophers for three centuries, and the effects of their discussions are felt in every department of science. Naturally so. Since it lies in the very nature of epistemology to question the capability of man's mind to contact reality and to know what things are in themselves, the validity of all knowledge, and consequently also of science, is at stake. The foundations of human knowledge are challenged, examined, and frequently attacked. An acquaintance with this problem and its possible solution will be, therefore, a matter of prime importance for every seeker of truth and for every student of philosophy.

The present book is intended for those who have no previous acquaintance with the subject. In accordance with this purpose, the author has endeavored to place the problem in its proper historical setting, showing its origin and development, without confusing the issue with a large amount of historical detail. For the same reason, the subject is treated in a constructive manner, seeking a positive solution of the epistemological problem rather than giving

an extensive criticism and refutation of the individual opposing systems of thought. The language, so far as consistent with the matter under discussion, is plain and simple, avoiding what Hugh S. Elliot styles "sesquipedalian verbiage." Much of our modern philosophical jargon is so well-nigh incomprehensible as to make the underlying ideas opaque: unintelligibility is not necessarily depth. Obscurities, of course, remain, because the nature of knowledge itself is obscure; no amount of words will ever be able to clarify completely the mystery of the mind.

As for the plan of the book, the first part treats of the possibility of valid knowledge in general. The second part then takes the sources of knowledge (experience and intellection) and examines them in their individual manifestations — consciousness, sense-perception, ideas, judgments, reasoning. The investigation arrives at the conclusion that our sources of knowledge are essentially valid and trustworthy.

It is the hope of the author that this book, like his *Science of Correct Thinking*, will be of value as general reading, as supplementary to classwork, and as a textbook for students. The problem is vital and deserves concentrated study.

June 7, 1936. - C.B.

PART I

**THE POSSIBILITY OF VALID
KNOWLEDGE**

Chapter 1

STATEMENT OF THE PROBLEM

KNOWLEDGE IS AT ONCE THE SIMPLEST AND THE PROFOUNDEST OF human experiences.

Nothing seems more plain to the ordinary man, and more beyond the possibility of any doubt, than the everyday facts of his knowledge. He is utterly convinced of the truth and certainty of the happenings in and around him. It never enters his mind to question the validity of his convictions concerning the knowledge of his experience. We may imagine him sitting in his lounging chair before a window and communing with his thoughts:

“It is certainly pleasant to sit here in comfort and watch the world go by. People are hurrying home from their business, chatting noisily with one another as they walk along the street. The sun appears flatter, larger, and redder every minute, as it slowly sinks in the west, and little by little the blue of the sky seems to turn into fire and gold. Soon the darkness will be here, and I shall see the distant stars. I did not think the wind was so very strong, but I see that it broke a branch from the tree in the square opposite. It is much colder than it was yesterday; I believe that will cause a frost tonight. The air is very raw outside. I ought

not have gone without a topcoat this morning. I believe I have caught a cold; I felt miserable all afternoon, I had a headache, the old pipe didn't taste, and my mind was so foggy that I couldn't control my thoughts properly, and I made a number of errors. I am not myself now. I must see my physician tomorrow; he knows my body almost as well as I know my soul."

All this seems so simple and matter-of-fact, and the knowledge contained in these statements seems so obvious and transparent, that we should scarcely consider it worthy of second thought. Much less should we think that philosophers could discover any deep and mysterious problems hidden in the desultory musings of an old gentleman seeking comfort in his easy-chair. Such, however, is precisely the case.

FACTS AND KNOWLEDGE

Many things are directly mentioned as existing, and a spontaneous conviction is expressed regarding 'facts' and 'knowledge,' in the self-communing quoted above. He 'watches the world go by.' So he is sure that there is a real world of substance, an existing universe of tremendous magnitude, consisting of earth and sun and stars. He may have no conception of the exact dimensions of this universe, nor of the distance and volume and nature of the stars; but he is sure that they are really there and that he does not merely imagine them. He speaks of *space* and *space-relations*: for people are walking 'along the street,' there is a 'square opposite,' the sun is 'sinking in the west'; he

notices a 'here' and 'there,' an 'outside' and 'inside.' He mentions *time* and *time-relations*: 'yesterday,' 'tonight,' 'tomorrow,' 'soon'; and the elements of succession in time are designated by the phrase 'every minute.' *Mathematical quantities* are affirmed: 'square,' 'larger,' 'flatter.' And also *numerical quantities* appear: 'people,' 'stars,' 'tree.' He notices the relation of part to whole in the 'branch' that is broken off the 'tree.' There are *qualities*, like 'blue,' 'strong,' 'cold'; *actions*, like 'walking,' 'sinking,' 'broke off'; *reactions*, like 'caught a cold,' the branch 'broken' by the wind; *posture*, like 'sitting in comfort'; habit us, like 'being clothed with a topcoat.'

Facts of *sense-experience* are enumerated: he 'sees' the things about him on the earth and in the sky; he 'hears' people chatting; he 'tastes' his pipe; he 'feels' sick; he is 'conscious' of his body. And so, too, facts of *intellectual experience* are noted: consciousness of the Ego or 'self,' 'thoughts,' 'knowledge,' 'soul'; states of mind, like 'belief,' 'errors'; states of will, like 'I must,' 'I ought not.'

He is aware of the great distinction between his self and things-other-than-his-self; between mind and matter; between living and inanimate things; between the subjective and objective; between the ideal and the real; between substantial and accidental being; between appearance and reality; between knowledge and opinion; between truth and error; between certainty and probability.

And many other things are contained in the data of his musings by *implication*. He is convinced that his senses, by and large, give him a true picture of the world about him and that he can trust them in their function of bringing the

world into contact with his mind by means of the sense-organs of his body. He is also convinced that his intellect, through judgment and thought, can acquire a knowledge of the world and of himself which is true and valid and certain. He realizes that his mind can make 'errors' and that appearances may deceive (as when the sun 'appears' flatter, bigger, and redder, and when the sky 'seems' to turn into fire and gold); but he also realizes that his mind can detect errors and correct deceiving impressions, finally arriving at truth. Furthermore, he knows that truth is objective, that his mind does not fabricate truth but merely discovers it, and that his mind will possess *truth* only when it agrees in its judgments with the things *as they are in themselves*.

SPONTANEOUS CONVICTIONS

Facts of everyday experience, such as those mentioned above, could be multiplied indefinitely. The ordinary man has a *spontaneous and unshakable conviction* that they are genuinely true. No amount of argument could convince him that his knowledge is not valid. He may not be very clear in his own mind about the scientific and philosophic grounds and proofs for this conviction, but of the reality of the world and of the truth of the facts he entertains not the slightest doubt. His common sense tells him that he is right. Every moment of his life, from the cradle to the grave, confirms his convictions that the world outside and around him is as he experiences it to be and that his knowledge of it is a correct insight into its reality. The whole substance of these

convictions can be summed up in this: ' *the world is objectively real and man has a genuine knowledge of it as it is.*

They are not forced convictions, accepted by the mind against its better judgment; rather, they are spontaneous for the very reason that they are the *natural* and *obvious* interpretations of the things and happenings in which man lives, and all together they form a system of knowledge which agrees with the demands of his rational nature. Man lives with and by and in these convictions, and these convictions are found by daily experience to be in accord with the facts as he knows them. Hence, he never questions their truth and validity; to him they are self-understood and self-demonstrative, and he feels perfectly safe in their possession.

This, of course, is strong *presumptive evidence* in their favor. If man's whole life can be regulated by them, in a practical as well as in a rational manner, then it is a *prima facie* proof that he is right in his assumptions. It would, then, seem superfluous for the scientist and philosopher to investigate the grounds and reasons of these spontaneous convictions. But such is not the nature of the human mind in its insatiable desire for deeper and more extensive knowledge. Man's mind simply cannot rest satisfied with the obvious and transparent explanation of facts. The urge for knowledge prompts him to investigate the *foundations*, the *ultimate grounds and reasons*, the 'how' and 'why,' of these spontaneous convictions.

THE PROBLEM OF KNOWLEDGE

It is this urge for knowledge which accounts for the rise and development of the *sciences*. Not satisfied with the superficial appearance of things, as the ordinary man sees and knows them, chemistry searches for the component elements of bodies, their activities and energies, their nature and qualities, their workings and the laws of their combinations. Gases (e.g., air), fluids (e.g., water), and solids (e.g., stones) are now understood to be, not bodies consisting of homogeneous material, but chemical compounds of very divergent elements united in definite quantities according to definite proportions under definite laws through the expenditure of definite amounts of energy. Not satisfied with the ordinary explanations of physical happenings in nature, physics attempts to discover their underlying causes and to chart their course of action from start to finish. Not satisfied with the common view that life in all its phases and functions is an inexplicable mystery, physiology and biology and kindred sciences have probed deeply into the hidden recesses of living organs and tissues and have wrested from them many secrets hitherto unsuspected. Many things concerning life have advanced into a clearer stage of scientific knowledge: among others, cell organization and function, the origin and growth of organisms, bacterial infection with corresponding medical treatment and international disease control, aseptic surgery, the proper distribution of nutritive values in foods. Similar progress has been made in the other sciences, due

to the urge for deeper knowledge inherent in the human mind.

All of this shows that scientific investigation of such problems is not a futile occupation. In many instances age-old spontaneous convictions have been confirmed by science, and in other instances they have been disproved. Many supposedly certain truths have had to be discarded, to give place to more reliable information. Thus, to mention a case in point, the Ptolemaic geocentric system, in which the earth was considered to be at the center of the universe with the sun and moon and stars revolving around it, has been proved by science to be false and has had to make room for the Copernican heliocentric system, in which the earth was relegated to the secondary position of one among many planets revolving around the sun.

This one instance has an important bearing on the problem of spontaneous conviction and knowledge. From the standpoint of human experience, nothing appears more plain than that the sun revolves around the earth. Yet we now know that the moon does, and the sun does not; but to all appearances *both* sun and moon travel through the sky in the same way. Similarly, due to the atmospheric refraction of light, both sun and moon are seen in the east before they are above the horizon, and in the west they are seen *after* they are below the horizon. Both are seen as deep-red in color when they rise and set; and both balloon out to a number of times their normal size, with bulging sides and flattened upper and lower poles; they shrink as they ride to the zenith and grow larger as they descend. Actually, however, the sun and the moon do not increase

and decrease in bulk, and at no time are they red in color. Again, the sun never actually grows warmer in the course of the day, nor is it any hotter in summer than in winter, nor does it change its position in the sky during the seasons of the year: its position in the firmament and its temperature are always the same. But the testimony of our senses seems perfectly clear regarding these changes, and mankind for thousands of years has had a firm, spontaneous conviction of the truth of this testimony. And even though science has furnished indubitable proof that our spontaneous conviction is wrong, our sense-experience still testifies to the same phenomena as before. Of course, there is an explanation for these phenomena but the fact remains that *spontaneous convictions can be radically wrong*, even when based on apparently irreproachable evidence of the senses. This, as will be seen later, is borne out by many instances besides the case mentioned above.

From the above it will be clear that the philosopher has a right to question the validity of the spontaneous convictions of man and to investigate their claim to truth and certainty. Just as it is necessary to examine the foundations of the ordinary man's views on nature and physical phenomena, so philosophy needs to lay bare the ultimate grounds and reasons of man's knowledge and spontaneous convictions, in order to see whether they will survive the test of a critical examination in the light of reason. If they survive, then they will be so much the firmer, since they will rest upon a scientific foundation; if they are disproved, then they must be discarded as obsolete and irrational, the same as many naive and unscientific ideas of a bygone age

regarding physical phenomena and their causes. Man is a part of nature, and his knowledge is also a phenomenon of nature; as such it should be analyzed and examined in its origin, development, and truth-value, to see whether it really gives us a true interpretation of the world around us and can lead us to a well-reasoned certitude. For that is the purpose and function of philosophy: to investigate and demonstrate the ultimate grounds and reasons of things.

To the ordinary man nothing seems simpler than his knowledge; but to the philosopher the problem of knowledge is by no means so simple as it seems. The speculative mind of the philosopher discovers a multitude of knotty questions which puzzle him sorely and for which he would fain find a solution. He is not at all sure that the spontaneous convictions and beliefs of the ordinary man deserve the credence accorded them. Science has disillusioned man regarding many of his century-old notions and convictions; and science itself has gone through many battles of conflicting opinions and hypotheses, reversing its conclusions in more than one instance. It is, therefore, no idle question to ask: What can we know? How far can the mind of man reach? Is valid knowledge really attainable? Is truth objective? Can we be absolutely certain about anything?

The *inductive* sciences, such as physics, chemistry, astronomy, geology, biology, physiology, and anthropology, are all based on ideas, principles, and laws derived from the objects and operations of nature, and the knowledge acquired in and through these sciences is almost entirely the result of sense experience and experiment. Even the

deductive sciences, like arithmetic, algebra, geometry, trigonometry, and calculus, are based on the ideas of quantity derived from space and number in material nature. The sciences, therefore, depend upon the validity of sense-perceptions and intellectual concepts to guarantee the foundations upon which they rest. Science, after all, is a body of universally applicable truths, formulated by the intellect as the result and expression of innumerable inductions and deductions. The value of the sciences will, therefore, necessarily remain in doubt until philosophy has given a satisfactory account of truth, certainty, and the ultimate validity of human knowledge in general. Thus it is imperative to vindicate the validity of knowledge both from the empirical and intellectual side, because science is the combination of both these phases.

EPISTEMOLOGY, THE SCIENCE OF KNOWLEDGE

Epistemology (from the Greek, *ἐπιστήμη*, knowledge, and *λόγος*, doctrine) is *the science of the validity, or truth-value, of human knowledge*. It is a 'science'; that is, it is a definite body of truths, derived from reasoned demonstrations of causes and reduced to a system. It is the 'science of *human knowledge*.' Here we have the general subject-matter of epistemology: it is not the purpose of this department of philosophy to investigate the nature of the human mind and its faculties, but that phase of the mind's activity which we designate by the term 'knowledge.' It is the 'science of the *validity, or truth-value, of human knowledge*.' This is the special or formal subject-matter of epistemology,

distinguishing it from the other departments of philosophy and from every other science. The sciences are concerned with knowledge, because they increase our knowledge of things; but they do not treat of knowledge from the standpoint of its 'validity' or 'truth-value.' It is the purpose of epistemology to submit our knowledge to a critical examination and investigate the *rational grounds* on which it rests, so as to discover whether and why we are justified in having the spontaneous conviction that our knowledge is valid and true in its claim to be a faithful interpretation of reality.

The definition shows us in what way epistemology differs from logic and psychology — two sciences closely related to epistemology. *Logic* is the science of 'correct' thinking. It gives us the laws and methods which we must follow, if we desire to avoid error and inconsistency in our mental acts; it is concerned chiefly with the proper arrangement of our ideas, judgments, and argumentations, so that a legitimate conclusion can be drawn from given truths. *Psychology* is the science of the soul in its nature and activities. This embraces everything pertaining to the soul of man, including knowledge. But so far as knowledge is concerned, psychology endeavors to lay bare its origin and nature, rather than its validity or truth-value. *Epistemology*, as a special science, leaves aside the formal correctness, the origin and nature of the act of knowledge, and seeks to establish its 'validity' and 'truth,' in so far as it is supposed to be a knowledge *of things*. For that is a peculiarity of human knowledge: we are convinced that it actually makes us acquainted with reality and gives us a true conception of

reality as it is in itself. This conviction, however, cannot simply be assumed; it must be established beyond reasonable doubt, otherwise philosophy and science will be without secure foundation. It is plain that, because of the close relationship existing between logic, psychology, and epistemology, epistemology must at times reach over into the fields of the other two sciences, because an understanding of the laws and nature of thinking is necessary to form a proper judgment about the truth-claim of knowledge. As such, then, epistemology differs from logic and psychology.

The term 'epistemology' is of comparatively recent origin. Formerly it often went under the names of 'applied logic,' 'material logic,' 'critical logic,' or 'noetics.' Now it is customary to separate this part of philosophy from logic and treat it as a special science. The reason for this procedure lies in the fact that the problem of knowledge has become the major philosophical problem of the past three centuries. This does not mean that the validity of human knowledge had received little attention in the preceding ages. It had been discussed since the very beginnings of philosophy in ancient Greece; but it has never held the predominant position in the minds of thinkers that it occupies today. Today it is the problem of philosophy. The importance of the problem will become apparent as we advance in our investigation.

Epistemology is sometimes called *criteriology*. But there is a distinction between the two. Criteriology, as the term implies, is the science of the *criteria of truth*. The criterion of truth is the norm or test or standard which enables us to

distinguish truth from error. Any theory of knowledge, to be complete, must treat of the criterion of truth; but there are many other questions involved in the validity of knowledge. Criteriology, therefore, is only a *part* of epistemology and as such does not cover the entire field usually assigned to what is known as the problem of knowledge.' Epistemology, on the other hand, considers this wider and more fundamental problem in all its phases. Criteriology asks the question: What distinguishes truth from error? Epistemology asks the question: Is our knowledge of things objectively valid and true? Plainly, we can inquire into the existence and nature of the criterion of truth only after we have established the prior fact of the validity, or truth-value, of our knowledge in general.

This, then, is the problem which confronts us: To investigate human knowledge and seek to determine the *rational grounds* upon which the *validity* of our spontaneous convictions are based. If we can establish this validity, these convictions will be critically and philosophically justified; if we cannot, our common and scientific knowledge must be considered to be nothing better than conjectures which may give us more or less probability but never the security of philosophic certitude.

SUMMARY OF CHAPTER 1

The act of knowledge seems a very simple thing; it is, however, a rather mysterious and profound experience.

1. *Facts and Knowledge.* To the ordinary man his knowledge is without question *valid*. This refers as well to intellectual knowledge as to sense-knowledge.

2. *Spontaneous Convictions.* Man has the spontaneous conviction that the world is objectively real and that his knowledge of it is true. He possesses many convictions of this sort regarding physical, intellectual, and moral matters. The convictions are *natural*, and as such they have a strong presumptive value. The philosopher, however, feels the necessity of inquiring into the *ultimate rational grounds* of these spontaneous convictions.

3. *The Problem of Knowledge.* The natural urge for knowledge accounts for the progress of the sciences. Science has disproved many spontaneous convictions of the past, for instance, the conviction that the sun moves around the earth. The truths of science depend on the validity of sense-perception and of intellectual concepts. Hence, it is necessary to establish the validity of knowledge.

4. *Epistemology.* It is the *science of the validity, or truth-value, of human knowledge*. Epistemology is also called 'applied logic,' 'material logic,' 'critical logic,' or 'noetics.' *Criteriaology* is a part of epistemology.

Chapter 2

IDEAS FUNDAMENTAL TO THE PROBLEM

BEFORE WE CAN UNDERTAKE THE INVESTIGATION OF THE PROBLEM of knowledge as such, it will be necessary to examine and define the ideas underlying the problem. Altogether too much confusion arises from a loose use of terms, and this obscures the issue and hampers proper thinking. In giving these nominal definitions it should be borne in mind that in no way do we intend to prejudge the fundamental validity of these ideas. Their ultimate value will have to be determined by the outcome of our investigation as a whole. But we must begin somewhere, and the ideas and terms used must have some definite meaning to start with. We, therefore, accept these ideas and terms in their obvious and current meaning. It is in this meaning that the problem has originated, and it is precisely in this meaning that the problem has significance. Ideas such as 'knowledge,' 'truth,' 'error,' 'certitude,' 'doubt,' 'subject' and 'object' have a distinct connotation in the minds of the ordinary man, and it is their ultimate validity which is at stake. Hence, the signification of such ideas must be clear before we can intelligently proceed to the problem itself.

KNOWLEDGE

When we speak of the 'problem of knowledge,' it is not a question whether man possesses 'knowledge.' That is a fact which no one denies. So we must begin with the idea of 'knowledge.'

Knowledge is a primary fact of human life and experience. Everyone understands what it means 'to know,' 'to have knowledge.' But when we attempt to explain and analyze this idea, we immediately encounter difficulties. Just because it is a *primary fact of experience*, the idea of 'knowledge' eludes every effort at an exact definition. We can point out certain *characteristics* of 'knowledge' and adduce definite *instances* of 'knowledge,' but we cannot really define it. 'To know' is on a par with 'to see,' 'to taste,' 'to touch,' 'to imagine,' 'to will.' Man is simply conscious of these states of his being and gives them a name; and thus he arrives at the idea and the term. It is useless to try to explain to a man born blind what 'color' or even 'seeing' is; just as it is useless to explain to a man born deaf what 'sound' or 'hearing' is.

We can place a man in a certain position and say to him: 'Open your eyes and tell me what you see across the park.' 'I see the Court House.' 'You are sure of it?' 'Yes, I am sure of it.' 'Then you *know* that the Court House is there.' Or we can say to him: 'Listen; do you recognize the melody?' 'It is the Funeral March of Chopin.' 'Good; then you *know* the melody.' Again, we may notice that he looks ill and ask: 'What is the matter?' 'I have a headache.' 'Well, then you

know what pain feels like.’ And so on. It is the experience of this sort which constitutes ‘knowing’ and ‘knowledge.’

Now, there are three elements which enter into knowledge: the knowing *subject*, the known *object*, and the *mental act of knowing* (cognition). The ‘subject’ is the one who knows; the ‘object’ is the thing that is known; and ‘cognition’ or ‘knowing’ is the mental act which makes this object known to the subject.

The *subject*, the knower, is man, as we notice it in the phrase: ‘This man knows his business.’ Taken individually, it is the Ego, the ‘I myself,’ who am the knowing subject, for we say: ‘I know this house, this game, this boy.’ All our activities are referred to the Ego as the subject. We become aware of this, if we reflect upon the following expressions: ‘I walked a mile; I saw an accident occur; I feel a pain in my side; I taste garlic in my food; I smell a pleasant odor in the kitchen; I thought about the depression; I know about the plans of my friend; I was conscious of the act.’ Knowledge, then, as a mental activity, belongs to the *Ego*, the *self*, as the ‘subject’ who knows. And it is in this sense that the idea of ‘subject’ must be taken in the epistemological problem of knowledge, because that is the spontaneous conviction involved in our way of thinking.

The *object* of knowledge is anything and everything that is, or becomes, or can be, known by man. According to man’s spontaneous conviction the objects of his knowledge comprise his own self, various conscious states of his self, and also realities-other-than-self. That he knows his own self, is clear from expressions like these: ‘I myself will go; I am myself and no other.’ That he knows his own conscious

mental states we have seen in the preceding paragraph. That he knows realities-other-than-self, is a plain fact which he manifests in numberless judgments of everyday life: 'The sun is shining; the wind is blowing; the meal is good; this building is tall; some roses are red.' In all such judgments the ordinary man refers his knowledge to some object, and he is sure that the object is as real as the subject. Whether his common-sense view that such 'realities-other-than-self' belong to an exterior world with an independent existence of their own outside man's mind, is precisely one of the problems to be solved. But that every act of knowledge must be a 'knowledge of *something*' and therefore refer to some 'object,' is perfectly clear and is disputed by nobody.

The 'object' becomes known to the 'subject' by the *act of knowing*. This act, of course, takes place in the subject or knower. It is a *unitive* act, in as much as it brings the object and the subject into contact with each other, thereby rendering the object 'present to' the subject and making the subject aware' of this presence of the object. Before being known, the object is merely an 'object-in-itself'; but through and in the act of knowing it now becomes an 'object-to-the-mind.' And it is by becoming an *object-to-the-mind* that a thing becomes 'known.' Somehow or other, then, an external physical object (if there be such) must become united to the mind of the subject by means of the cognitional act and be presented to the Ego as an 'object-to-the-mind,' in order that it can become 'known' by the subject; in other words, the object must become *intra-mental* and *intra-subjective*, before it can be known. A simple example may make this clearer. I see a burning

house and 'know' it to be burning. How do I get to know this fact? The house is perhaps a hundred yards from where I stand. Surely my mind does not leave my person, cross the intervening space, and physically contact the flaming building; nor does the burning house leave its foundation, travel over to me, enter my mind, and then actually burn inside my person. Nevertheless, the burning house and my mind must become united in some way, or I could not *know* that the *house* is burning. Since the house has no physical presence inside my mind, it must have a *cognitional presence* there by means of sense-perception and thought. An object, then, in order to become 'known' by the subject, must acquire an intra-mental and intra-subjective presence or existence, must become an 'object- to-the-mind,' must have a 'mental objectivity,' must become an 'ideal being.' The very act of knowledge demands this sort of presence of the object in the subject; otherwise no union would take place between subject and object, and 'knowledge' would not be possible. The question, of course, arises: Has this object (for instance, the burning house mentioned above) a real, extra-mental existence of its own outside the self and the mind, independent of the cognitional existence which it has in the mind in the act of knowledge? The ordinary man is convinced that it has an objectively real existence outside the mind; idealists on the contrary, assert that we can know nothing but what takes place subjectively in our mind, and that we therefore have no right to affirm the existence of any thing-other-than-self. And so we again are face to face with the fundamental problem of knowledge. Whatever the solution, this much is clear and recognized by all: an

‘object,’ in order to be known, must be *cognitionally present* in the ‘subject’ in the ‘act of knowing.’

The ‘subject,’ the ‘object,’ and the ‘act of knowing’ are thus the essential elements necessary for knowledge. Whatever pertains to, or proceeds from, the subject is *subjective*; and whatever pertains to, or proceeds from, the object is *objective*. The state or condition of ‘being subjective’ or ‘being objective’ is then styled ‘subjectivity’ or ‘objectivity.’ And anything that pertains to, or proceeds from, the act of knowing or cognition is termed *cognitional or intentional*. Knowledge will thus be either subjective or objective; viewed from the standpoint of the subject who knows, it is ‘subjective’; and considered as referring to the object which is known, it is ‘objective.’ So much for knowledge as it exists in the knower.

TRUTH AND ERROR

Knowledge has the quality of *truth* and *error*. The absence of knowledge in a being capable of possessing it is termed ignorance; thus, a man who does not know whether zinc is an element or a compound is in ignorance as to the nature of zinc. The absence of knowledge in a being incapable of possessing it is termed *nescience*; an animal, like a dog, does not and cannot know whether zinc is an element or a compound, and he is in a state of nescience regarding this fact.

It is only in the act of knowledge that we have truth and error. Truth and error enter into our knowledge, when this knowledge is expressed in *judgments*; that is, when we

affirm or deny something of something else. If what we affirm is really so as we affirm it to be, we have truth; but if it is not really so, we have error. And reversely, if what we deny is such that it is correctly denied, we have truth; otherwise we have error. For instance: I take a piece of metal in my hand, examine it, and state mentally, 'This is brass and not gold.' I both affirm and deny something here of the metal in my hand; I affirm it to be 'brass' and I deny it to be 'gold.' If this metal is really brass and not gold, then my double assertion (affirmation and denial) contains truth; but if it be really gold and not brass, then I am mistaken, and my double assertion contains error. As long as I merely look at the metal and form an idea of it, my knowledge is neither true nor false; but as soon as I apply an idea to the metal and mentally assert (affirm or deny) something about this metal in a judgment, then this judgment-knowledge automatically becomes true or false, depending upon whether or not my judgment and assertion corresponds to the reality-in-itself. Truth and error, therefore, are found in the judgment. This is mental or *logical truth* and it consists in the *conformity of the mind to the thing*. *Logical error* is defined as a *disconformity of the mind to the thing*. When we speak of truth as the 'conformity' of the mind to the thing, we do not mean that the 'nature' of the mind must conform to the 'nature' of the thing; we mean that the mind must conform to the thing 'cognitionally' in its judgment.

There is, however, also *truth* in the *things*. We have, for example, a very definite notion of the metal called 'silver.' This notion or idea of 'silver' involves a number of subordinate ideas regarding the color, the specific gravity,

the malleability, the hardness, the chemical constitution of silver; and this notion is a norm or standard to which a metal must conform in order to be designated 'silver.' If the metal agrees with this standard, it is true silver, otherwise it is false silver. The silver used in jewelry and that used in government coins is true 'silver'; but German silver, being an alloy of copper, zinc, and nickel, is false silver, because the real 'silver,' being a chemical element of its own, contains none of these metals. When a stenographer copies a letter, and the copy does not agree with the original, then the copy is false or erroneous; only if the copy agrees in every respect with the original is it considered a true copy. When, therefore, objects conform to a recognized mental norm or standard, they are said to possess 'truth of being' or 'ontological truth.' *Ontological truth* is thus defined as the *conformity of a thing to the mind*. Reversely, *ontological error* consists in the *disconformity of a thing to the mind*.

From the above explanation it will be clear how truth in general must be defined: it is the *conformity between mind and thing*. *Error in general is the disconformity between mind and thing*. Men universally distinguish between truth and error and consider them irreconcilable opposites. In epistemology we must deal with *logical* truth and error, because its problem is concerned with the validity of human knowledge. The fundamental question is this: Can the mind *transcend itself*, reach to reality outside itself, *conform to reality*, and thereby acquire *truth*? There can, of course, be no question whether men think they can acquire a true knowledge of reality; all men have a natural, spontaneous, universal, and unshakable conviction that their mind knows

many truths which give them a trustworthy insight into the nature and qualities of things. They are certain that their knowledge *does* conform to reality. The *fact* of this conviction concerning the possession of logical truth is acknowledged by all; whether and how far this conviction is *justified*, will have to be determined by the critical examination of all the data and facts in the case. At present we are merely interested in acquiring a clear conception of the ideas and terms involved. For that purpose it was necessary to specify the exact meaning of 'truth' and 'error' in so far as they may be found in human knowledge.

DOUBT, OPINION, CERTITUDE

Regarding many things man is certain that he possesses knowledge. He is equally certain that there are far more things of which he is totally ignorant. Again, he is conscious of the fact that he has made many errors in the past and that much of his present knowledge may be erroneous. He realizes also that he has no exhaustive and fully adequate knowledge of things, not even of himself. The consciousness of all this is reflected in his mental attitude toward the things he knows or thinks he knows. These attitudes are *doubt, opinion, and certitude*.

Doubt is that state of the mind in which a *suspended judgment* ensues, due to the mind's inability to decide whether the judgment is true or false. If the mind can discover no reasons, or practically no reasons, which enable it to come to a decision regarding the truth or error of its judgment, then the doubt is *negative*. If it has discovered

reasons, but if they are of practically equal weight for and against the truth of the judgment, thereby making a decisive judgment impossible, then the doubt is *positive*. In both cases the result is the same: the fear of error cannot be overcome, and the judgment remains suspended. For example: Dark, heavy clouds are scurrying across the sky, and it looks as if it would rain. But the wind is high, and the clouds are traveling fast. Will it rain? The appearance of the weather indicates rain; but, the high winds may drive the clouds away. It might rain, but I fear it will not, and so I suspend my judgment: I doubt. Another case: Will the Army or the Navy win this year's football game? Both have brilliant players; the one team is noted for its power, the other for its deceptive plays. The situation is such that the mind can come to no real decision: it doubts. And so there are innumerable instances where man cannot overcome his doubts.

Opinion is a state of the mind in which it *decides* for the truth of a judgment, but with *fear of the possibility of error*. The best that the mind can attain with regard to the truth of its judgment is a certain amount of probability. The reasons are good on both sides of the question; but the mind realizes that reasons for making the decision are weighty enough to justify adherence to one side of the question rather than to the other. The fear of error, however, hinders the mind from giving an unqualified assent to the judgment; there is still lack of certitude. Here is a case in point: Will the communists continue to rule for any great length of time in Russia? The fact that they have ruled so many years is a good reason to assume that they

will. But the fact that their rule is imposed by force and is fundamentally contrary to human nature, is apparently a better reason to suppose that it cannot last. If I decide for the latter side of the question, I have an 'opinion' that the communists will not continue to remain in power for any great length of time. Or, supposing all the evidence in a criminal case has been presented in court, and it is circumstantial and conflicting. I may weigh this evidence and decide that the defendant is guilty, although I realize that there is good evidence against such a judgment: I have formed an opinion on the case.

Both in doubts and opinions there is lack of certitude. In doubts I can come to no decision, but in opinions I make a decision. In neither instance, though, can I overcome the fear of the possibility of error. The mind is in a condition of hesitancy and uneasiness and remains in this attitude as long as a prudent fear of error lingers on. As soon as this fear of error is definitely overcome, hesitancy and uneasiness vanish, and the mind is at rest in a state of certitude. [*atorexia ed.*]

Certitude is the state of the mind in which it gives a firm assent to a judgment *without fear of the possibility of error, due to recognized valid reasons*. Three elements, therefore, enter into the concept of certitude: the firm assent to the judgment, the absence of fear of possible error, and the understanding of the valid reasons which exclude this fear. The absence of the fear of possible error is the negative factor which distinguishes certitude from doubt and opinion, while the consciously apprehended valid reasons for the firm assent of the mind are the *positive* factor of

conviction or certitude. This, of course, does not mean that the mind is really infallible in these convictions and that error is impossible in all these judgments. What it does mean, though, is that the mind is subjectively certain of its grounds and does not fear the possibility of error; it is convinced that it is in possession of knowledge which is true and valid. The educated man and the savage alike are convinced that the sun is an existing reality in the sky. The savage, furthermore, is convinced that the sun actually travels through the sky from east to west in the course of the day, while the educated man is certain that it does not; one of these two (subjective) certitudes must be wrong, because they are contradictory and mutually exclusive and cannot be true at the same time. While, then, subjective certitude does not exclude the possibility of error, it does always exclude the *fear* of error in the mind of him who possesses certitude.

Concerning the *motive of certitude*, which influences the mind in giving a firm assent to a judgment, there exists a difference in value; and this difference in value produces increasing degrees of certitude. We are conscious of the fact that we are not equally certain of all truths, even though all these truths are certain to our mind. There is a considerable range of 'more and less' in our certitude. Thus, I am sure beyond doubt that a country like China exists, even though I have never been there; but I am more sure of the existence of the United States than I am of China, for the simple reason that I live in the United States. So, too, I am convinced of the spirituality of my soul, because I can prove it to my mind beyond reasonable

doubt; but I am more certain of the reality of my body, because I have an immediate awareness of my body's presence. And so with many other truths.

There is *moral* certitude, *physical* certitude, and *metaphysical* certitude. *Moral* certitude is based upon a moral (not to be confounded with 'ethical') law, upon the customary natural conduct of human beings in a given environment and under given conditions. It has been observed that men under such circumstances act and react uniformly in the same way. We are, for instance, certain that 'Parents love their children.' While we realize that some parents do not conform to this law of human conduct, and that consequently we might be mistaken in individual cases, we feel certain that the law, generally speaking, expresses a truth. 'A nation, whose citizenry lives in reasonable comfort, is not prone to revolution,' is a similar truth which is morally certain. 'Youth is gay and craves excitement,' is another.

Physical certitude is based upon a physical law of nature, and the latter is considered to be uniform, necessary, and universal. Exceptions to such a law are impossible in the natural order of things. Only nature's Creator and Lawgiver could suspend the effects of a physical law. Such laws are, for example: 'Gases expand in heat'; 'water will freeze at sea level, when the temperature drops to 32° F.'; 'a body, whose specific gravity is less than that of water, will float in water'; 'two parts of hydrogen, when united to one part of oxygen, form water'; 'a magnet will attract iron.' In such and similar cases we are physically certain that our judgments are true. We have no fear that the opposite will

happen, except through a miracle. Physical certitude is far greater than moral certitude. Necessity rules in the physical laws; while in matters of customary conduct the human will can bring about individual exceptions.

Metaphysical certitude is based upon a metaphysical law, an exception to which is intrinsically impossible, because it would involve a contradiction in itself. We are utterly convinced that no power, not even the Omnipotent Himself, can change truths like the following: ' $2 + 2 = 4$ '; ' $7 + 5 = 20 - 8$ '; 'the part is smaller than the whole'; 'everything must have a sufficient reason for its existence and being'; 'every change demands an adequate cause'; 'a circle is no square.' There is an absolute necessity to these things which nothing can ever alter, and our certitude is in proportion to this recognized necessity: it is an irresistible certitude.

A mere glance at the truths contained in the judgments expressing these three classes of truths will show us that there are *increasing degrees* in our certitude regarding them. We have moral certitude concerning many things, but it does not give us the firmness of assent which we possess with respect to truths of the physical order; and the firmness of our assent in metaphysical certitude is far superior to that given to truths of the moral and physical order. All three classes of truths produce certitude in our mind; but the *motive* of certitude is greater in the one than in the other, causing a correspondingly firmer assent.

Once again, however, it must be remembered that our sole purpose here is to explain and delimit the idea of *certitude* as it is found to be present in our consciousness,

without intending to presuppose the reasonableness and justifiability of this idea. The fact is that we do possess these different types of certitude and that men in general are convinced of their validity. How far they are justified in this assumption is a question still to be answered in the course of our investigation. We may not prejudge the issue. Clarity in our ideas, however, is an essential requisite for rational discussion. We can hope to arrive at a correct solution of this difficult and important problem only when the fundamental ideas of 'knowledge,' 'truth,' 'error,' 'doubt,' 'opinion,' and 'certitude' are clearly understood in their relation to each other and to the problem at large.

These ideas are basic; they lie at the very root of knowledge; and their proper understanding should assist materially in preparing us to meet the problem of knowledge in an intelligent manner.

SUMMARY OF CHAPTER II

It is necessary to examine and define the ideas underlying the problem of knowledge.

1. *Knowledge*, being a primary fact of experience, like 'seeing,' 'hearing,' etc., is incapable of an exact definition. 'Knowing' is simply a matter of experience and consciousness. Three elements enter into knowledge: subject, object, and the act of knowing.

The *subject* is the one who knows — man, the Ego, the 'I myself.' The *object* is the thing known. Man knows his self, his conscious mental states, and realities-other-than-self. The *act of knowing* makes the object 'present to' the subject and makes the subject 'aware' of this presence of the object. In the act of knowing, an object becomes an 'object-to-the-mind,' an 'ideal being,' by means of its 'cognitional presence.'

2. Knowledge has the quality of *truth* and *error* in its judgments. *Logical* truth is the conformity of the mind to the thing; logical error is the disconformity of the mind to the thing. *Ontological* truth is the conformity of the thing to the mind; ontological error is the disconformity of the thing to the mind. *Truth in general* is the conformity between mind and thing; error in general is the disconformity between mind and thing. Men universally distinguish between truth and error and consider them irreconcilable opposites. The fundamental problem is: Can the mind *transcend itself*, *conform* to outside reality, and thereby acquire truth?

3. The attitude of the mind toward knowledge is threefold: doubt, opinion, and certitude.

Doubt is that state of the mind in which a *suspended judgment* ensues, due to the mind's inability to decide whether the judgment is true or false. It is either negative or positive.

Opinion is a state of the mind in which it *decides* for the truth of a judgment, but with fear of the possibility of error.

Certitude is a state of the mind in which it gives a firm assent to a judgment *without fear of the possibility of error*. The absence of this fear is the negative factor of certitude; the consciously apprehended reasons for the firm assent are the positive factor. There are *degrees* of certitude. If the *motive* of certitude is based on the law of customary human conduct, we have moral certitude; if it is based on a physical law, it is physical certitude; if it is based on a metaphysical law, it is *metaphysical* certitude: the firmness of the assent increases in this order.

It is the purpose of epistemology to investigate the validity of these ideas.

Chapter 3

SPECIFICATION OF THE PROBLEM

THE FIRST REQUISITE FOR A RATIONAL SOLUTION OF THE PROBLEM of knowledge is a clear understanding of the ideas and terms which underlie the problem as a whole. The preceding chapter has made us acquainted with these basic ideas and terms. The next requisite will be an exposition of the general *facts* which are *given* and *granted* by all, which form the common ground upon which all stand, which constitute the undisputed basis of the problem, and which are the universal starting point of all inquiry.

Knowledge we have. No one seriously doubts that we possess what is termed 'knowledge,' considered as a subjective state of the mind. What worries the philosophers is the firm and spontaneous conviction entertained by the generality of men, educated and uneducated alike, that this knowledge is a faithful representation of reality *as it is in itself*. They are not so sure that the ordinary man's claim to 'truth' in this knowledge is justifiable beyond reasonable doubt. They feel that these Spontaneous convictions must be critically investigated before their validity can be admitted. These convictions are obvious facts. We have them, and they cannot be argued out of existence. That they

produce in us a subjective certitude is also admitted as a fact; but what philosophers desire to establish is, whether this subjective certitude is grounded on *objective reality*. That is the vital question. It will be necessary, therefore, to make a general survey of these spontaneous convictions of mankind, considered solely as facts, in order to obtain a clearer conception of the problem.

CONVICTIONS BASED ON SENSE-PERCEPTION

All epistemologists admit that we have sense-perceptions, viewed as subjective states of our mental life. The knowledge obtained thereby is derived through various bodily senses; and man has the spontaneous conviction that this knowledge acquaints him with the reality of a material world.

There is the sense of *sight*. Nothing is clearer to the ordinary man than that what he sees is actually what and where he sees it to be. His own body, buildings, trees, fields and hills, the sun and the moon and the stars — he is convinced that he sees these things simply because they are parts of the outside world around him. They are present, whether he sees them or not; they have an existence of their own, independent of his perception of them, and they will retain their reality even when he is blind or dead. So, too, color and light are objective realities for him: the sun and the stars really shine, the rose is really red, and the grass is really green. The whole matter is simply too evident to be doubted. He feels so safe in accepting this knowledge conveyed to him by the sense of sight, that he would rather

question the sanity of anyone doubting these things than entertain any misgivings concerning this knowledge itself.

Taste and *smell* confirm him in his conviction of the reality of things. Sugar is sweet, acid is sour, quinine is bitter, brine is salty. The ordinary man is certain that these objects possess these *flavors* as objective qualities. He is also convinced that objects emit real odors. Odor may be fruity, as in the peach, or spicy, as in cloves, or flowery, as in the rose, or foul, as in carrion, or scorchy, as in burned wood, or resinous, as in pine pitch. But whether agreeable or disagreeable, he always refers these flavors and odors to things which are real and independent of his own person.

Hearing, according to his conviction, perceives sounds which emanate from actual objects. The human voice in its speech, the rapturous melody of the nightingale, the roar of the lion, the crash of the thunder — they actually exist in nature as he hears them. Sound to him is real; and he simply cannot understand that, in the absence of hearing in men and animals nature would be totally devoid of sound.

The sense of *touch* also reveals various qualities which it considers to be objectively real. What is commonly called 'the sense of touch' consists of a number of distinct senses. The skin senses convey the sensations of temperature, pain, and touch proper. The kinesthetic or muscle sense is located in the muscles, tendons, and joints, and makes us aware of the movements and position of our bodily limbs and also of resistance and pressure. The organic sense has its seat in the internal organs of the body and enables us to perceive hunger, thirst, nausea, and general bodily well-being. How far these senses are fundamentally distinct is a

matter for the psychologist to decide. Whatever their nature, the ordinary man is certain that they reveal to him his own body and other bodies, together with definite qualities, which are real in the world of physical objects.¹

Besides the senses just enumerated, the human organism possesses what may be roughly designated the internal sense because they enable man to apprehend facts of a subjective character in a sensuous manner. We are not concerned here with their ultimate nature and difference, but with certain undeniable facts of internal experience in so far as they have a bearing on the problem of knowledge.

The *common* or *central sense* makes us aware of our sense-acts. It is the seat of sense-consciousness, notifying us of the presence of the perceptive acts mentioned above, of feelings, such as pleasure, grief, anger, desire, and of appetitive striving. The central sense enables us to distinguish in a concrete way between the various organs and perceptions and to locate them in the bodily system. That this is not a form of 'intellectual' knowledge, can be seen from the actions of animals. They manifest no intellectual knowledge, but they are conscious of the different kinds of sense-perceptions and of the various parts of their body. The main point here is that man is convinced of the reality of his body and of outside objects as revealed by the coordinating action of the central sense.

The *imagination* uses the material supplied by the sense-perceptions to form images of its own fashioning. Dreams are the product of the imagination. But man also uses his imagination creatively, constructing a world of fancy which exists nowhere but in his mind. Man is conscious of the

distinction between the figures of his fancy and the people of real life, between the pictured events of his dream and the actual occurrences of external happenings. During a dream he may be unable to recognize events as unreal, but upon awakening he becomes aware of their imaginary character. The essential difference between fancy and reality is perfectly clear to the ordinary man and forms one of his strongest spontaneous convictions.

Sense-memory recalls perceptions and events and recognizes them concretely as having been experienced before. It is able to 'locate' these experiences in their proper sequence of time and place. We not only remember the persons and objects we have seen before, but we also remember the time and place of seeing them. That these memory-images represent a reality distinct from these images, is another spontaneous conviction of man.

The connection of *instinct* with the problem of knowledge is slight. While instinct plays a prominent part in the life history of animals, its function in man is limited, due to the predominant part exercised by man's intellect in the ordering of his actions. It is the cognitive function which apprehends material objects as things either harmful or useful to the organism consequent upon their perception. The influence of instinct is noticed chiefly in actions which are necessary for the preservation of the individual and of the race. Whatever instinct may amount to in man, it is stimulated by external objects and events and always has a reference to external reality: such is man's natural conviction.

All senses convey knowledge of the *reality of the physical world* in some form or other. That, at least, is the view of the average person, and of this he is certain beyond doubt. How far this obvious, spontaneous conviction can be justified before the bar of critical reason, is precisely the duty of the epistemologist to examine and determine.

CONVICTIONS BASED ON INTELLECTION

We now come to *intellectual knowledge*. This is distinctly 'human' knowledge, because animals manifest no signs of it. Intellectual knowledge appears in three phases: *ideas, judgments and inferences*. We are not concerned here with the nature of the intellect as such; we are interested in its knowledge as found in these three products of mental activity. Whatever we may think of their validity and truth, we cannot seriously doubt that we have ideas and judgments and inferences. They are facts, and they lie at the very core of the problem of knowledge.

An *idea* is the intellectual representation of a thing. My idea of a thing is very different from my sense-perception of that thing. For example: As I walk along, I see a man. He is white of skin, six feet two inches in height, with black eyes and black hair, slim but muscular, and a slight limp gives him a somewhat halting gait. He wears a cap, a brown suit, a gray topcoat, blue socks, and black oxfords. This is the picture of an individual human being as he meets the eye and is perceived by the sense of sight. But my 'idea' of this man is that he is a 'bodily, living, sentient, rational substance'; in other words, this man is a 'rational animal.'

The sense perceives him in all his concrete individuality, with all the peculiar traits and characteristics which make him to be *this* man and differentiate him from every other human being. My 'idea,' however, apprehends him in those essential attributes which he has in common with all other human beings, leaving aside all the individualizing and differentiating marks peculiar to himself. Sense-perception, therefore, represents man in the *concrete*; the idea represents him in the *abstract*.

Passing on to the *judgments* of the intellect, we find that a judgment is an act of the mind affirming or denying one idea of another. Three factors are involved in the making of a judgment: two ideas which are known; the mutual comparison of these two ideas; the mental pronouncement of their agreement or disagreement. The intellect, for instance, consciously apprehends and compares the ideas 'tree' and 'plant'; it finds that they agree; then it pronounces this agreement in the judgment, 'The tree is a plant.' But on comparing the ideas 'tree' and 'animal,' the intellect perceives that they do not agree and then makes the pronouncement, 'The tree is not an animal.' If my assertion (affirmation or denial) in the judgment is correctly made, it is a true judgment; but if incorrectly made, it is false. Judgments, therefore, contain *truth or error*. It is just this characteristic of the judgment, that it contains truth or error, which makes the judgment such an important element in the problem of knowledge. Internal and external sense-perceptions present or represent things concretely, and ideas represent the essence of things abstractly; but judgments claim to express the truth about *reality as it*

actually is in itself. When I say, 'This man is an Indian,' I mean to assert that he *really* is an Indian; I certainly do not intend to convey the impression that I am merely combining the two ideas 'this man' and 'Indian' in my mind. In fact, the ordinary man never adverts to the fact that his judgment consists of a 'subject' and a 'predicate' and a 'copula'; for him his judgments simply express reality as he sees and knows it to be, and he is certain that his judgments do actually represent reality.

The same is true of *inferences*. The mind does not always perceive the agreement or disagreement between two ideas by a direct comparison of the two, so that it can make an immediate judgment about them. That 'Two plus two are four' I know from a mere analysis of these ideas, and that 'The sun is shining' I know by opening my eyes and looking at the sky; but that 'The human soul is a spirit' is something I can neither see with my eyes nor perceive by a direct comparison of these two ideas. If, however, I can bring in a third known idea with which, upon comparison, I find the two ideas to agree, then I am justified in saying that these two ideas agree with each other. This is inference or reasoning; and it is defined as the mental process by which, from certain truths already known, the mind passes to another truth distinct from these but necessarily following from them. That man reasons and makes inferences of this kind, is a fact of everyday experience. And man is convinced that these inferences, since they consist of judgments and lead to a final judgment, are a valid form of knowledge and contain truth regarding *reality as it is*. Whenever people argue among themselves about facts and events, about

politics or religion or science or sports or anything else, it is always with the conviction that these arguments can lead them to truth and valid knowledge. The deductive reasonings of mathematics and the inductive processes of the experimental sciences are all based on this assumption.

Man possesses also *intellectual consciousness*. He is aware of the intellectual acts of apprehension (ideas), judgments and reasoning, and also of other states and acts of his being, as love, hatred, sorrow, happiness, volition. Furthermore, man is conscious of *self*, of his own *Ego*, in the acts of thinking, willing, and sense-perceiving, and he recognizes his own self as the *subject* of these acts, the agent who performs them and in whom they occur. He is also aware that these acts in their varying forms differ among themselves, while he, in whom they take place and in whom they inhere as their subject, is *one and indivisible*. These facts are expressed by him in phrases like the following: 'I think,' 'I will,' 'I see,' 'I was angry,' 'I walk,' 'I am aware of myself.' These judgments show that man realizes that he consists of a body as well as of a mind and that these are different entities belonging to the same Ego. They also show that his Ego persists as an *unchanging, permanent reality* amid all the changing acts and states which come and go within his person. Finally, man perceives that, while his body is a part of his Ego, there are *other bodies* which do not belong to his Ego; there is, therefore, a *world* or universe distinct from his Ego, with an existence and reality of its own.

Such are the undeniable spontaneous convictions of man as manifested by his conscious states and expressed in his

judgments.

CLASSES OF TRUTHS

Truth, as we know, lies in the judgment. Not all truths, of course, are of equal value to man. That my shoe squeaks, is a truth of no importance, unless, perhaps, I were a burglar or a detective; so, too, the fact that there is a solitary cloud in the sky this morning, is not a truth which will startle mankind. Such truths are commonplace and mean little. But scientific truths have far greater value. That water, for instance, consists of one part oxygen and two parts hydrogen, is a truth the discovery of which meant a distinct advancement in human knowledge and progress, because it enabled man to acquire great quantities of these two useful elements. Philosophic truths possess even greater importance than scientific truths, because the validity of science depends upon them. Thus, the Principles of Contradiction and of Sufficient Reason underlie all being and knowledge and constitute the very foundation of the sciences. It will, therefore, not be amiss to classify the different kinds of truths as found in the judgments of the intellect, since the value of man's spontaneous convictions is closely connected with his insight into these truths. The validity of man's knowledge can be established only if the validity of such truths is established, and so it is well to know these *classes of truth*.

First of all, we possess *analytical* judgments, which contain truths *directly evident to the intellect* through a comparison or analysis of the ideas of the judgment,

without the aid of any immediate sense- perception or logical reasoning. For instance: 'The whole is greater than any of its parts'; 'a plane square incloses four right angles'; 'it is impossible that a thing exist and not exist at the same time'; 'something cannot be true and false at the same time'; 'everything must have a sufficient reason.' Such judgments, called 'first principles,' are immediately evident to the intellect by merely analyzing the ideas contained in them, provided the intellect knows what these ideas mean. They need no demonstration and no direct sense-perception to verify them. If I know what a 'plane square' is and what a 'right angle' is, a mere comparison of these two ideas will make it clear to the intellect that 'A plane square incloses four right angles,' one in each corner of the figure. Again, if I know what 'whole' and 'part' mean, it is evident to me that 'The whole is greater than any of its parts.' And so with similar axioms. Such principles are at the bottom of all knowledge, and they are, as all admit, indubitably present in our spontaneous convictions. Axioms, like the Principle of Identity, the Principle of Contradiction, and the Principle of Sufficient Reason, are used, consciously or unconsciously, in every act of reasoning and are considered to be universally, necessarily, and absolutely true.

Secondly, we have *immediate* judgments containing truths which are derived from direct experience through internal and external *sense-perceptions*. Here are examples: 'That lady Walking along the street has a package under her arm.' 'That boy is running.' 'I have a pain in my tooth.' 'I am thinking and Writing.' Such judgments refer to individual concrete facts, events,

persons, and objects. We do not arrive at the truth of these judgments through a mere analysis of the ideas contained in them. Take the judgment, 'That boy is running.' On comparing the ideas 'boy' and 'running' alone by themselves, independent of experience, I cannot know whether I should unite them into a judgment, because there is no necessary connection between the ideas 'boy' and 'running'; the boy might just as well be 'standing' or 'sitting' or 'walking.' That I actually judge, 'That boy is running,' is due to my actual experience of seeing him run. Such judgments, then, are not analytical but *synthetic*; they contain empirical truths, based on direct experience. As such, therefore, they are not considered to be universal, necessary, and absolute truths; they are contingent and experiential truths which may change with changing circumstances. A comparison between this and the foregoing group of judgments will reveal at a glance that the synthetic judgments have by no means the general truth-value of the analytical judgments, so far as knowledge is concerned.

The third class of truths are those contained in *mediate* judgments deduced by *inference* (reasoning) from '*first principles*.' These mediate judgments are based on self-evident 'first principles' or 'axioms,' but they themselves are not self-evident; it takes a process of reasoning to show that they follow necessarily from these axioms. Mathematical deductions are examples of this class of judgments. That 38,400 is divisible by 2,560 fifteen times is not in itself directly clear; but if we perform the division, or multiply 2,560 by 15, we can prove the truth of the

judgment. Similarly, that the square of the hypotenuse of a right-angled triangle is equal to the sum of the squares constructed on the other two sides, is clear enough when the proof is furnished by a process of reasoning: but it is not a self-evident truth like the statement that a plane square incloses four right angles. A mere explanation or comparison of ideas will not suffice in these cases to perceive the truth of such judgments by means of immediate intuition: mediate inference is required to establish the logically necessary connection between such truths and the axioms upon which they are based. However, once this connection is demonstrated, these *deductive* judgments are as true as their 'first principles,' unless it can be proved that man's reasoning powers are essentially invalid in their operations. Man's conviction is, of course, that he can reason in a valid manner. Provided, then, that man's reasoning powers are essentially valid, these mediate judgments derived from 'first principles possess universal, necessary, absolute truth.

The fourth class of truths is contained in *mediate* judgments which are the result of an *inductive process* generalizing the individual, concrete data of direct sense-perception into laws of a universal character. The generalizations and laws of experimental science are of this type. After careful investigation and extensive experimentation the intellect perceives the *essential* elements in a series of repeated phenomena and occurrences and then expresses the true cause in a definite judgment or law. It is not necessary for science to investigate every single case of the past and present; that,

in fact, would be impossible. Since it has arrived at a knowledge of the essential elements of the phenomenon in question, the law which the intellect has formulated has a universal and necessary value and applies with equal force to each and every phenomenon of that class. An instance will make this clear. It was noticed that the boiling point of water is always + 212° F. at sea level. Taking this as a starting point, scientists made a great number of experiments of boiling water at sea level, and the result was in each case the same: water boiled at + 212° F. Thus the law was formulated by means of a generalization: 'The boiling point of water is + 212° F. at sea level.' This being an essential characteristic of water, it was not necessary to take every drop of water on the globe to sea level and boil it; scientists know that it will boil, because such is the *nature* of water. Every such law is a mediate judgment which expresses a necessary and universal truth, based upon the Principle of Sufficient Reason and the Principle of Causality.

The above brief account furnishes us with a survey of the sources and main facts of knowledge as revealed in the spontaneous convictions of men. Sense-perception, intellection, and self-consciousness, all contribute their share toward the sum total of man's knowledge. There is one trait characteristic of all these spontaneous convictions: *man's knowledge is a faithful and genuine representation of reality as it is in itself.* And this reality is twofold: Ego and non-Ego; the ideal world of thought and the material world of physical objects; man himself and a universe distinct from man. And man's mind can transcend itself,

reach out and contact this outside world, assimilate it cognitively, and thereby acquire a *valid knowledge of things*. This is the sum and substance of the facts as given in man's convictions.

THE EPISTEMOLOGICAL PROBLEM

No one questions the fact that the ordinary man, whether educated or uneducated, has these spontaneous convictions. Philosophers all admit that man has these experiences, considered as 'subjective states' of his being, and that he is 'subjectively convinced' that these experiences reveal to him an objectively existing world-other-than-his-self. There is a vast difference, though, philosophers contend, between these experiences as such and the *interpretations* man makes of them. The facts they admit; but whether the physical world as real (if there is a real world) actually corresponds to the world *as perceived*, that is a different question entirely. Of course, the ordinary man judges and is convinced that the two correspond; however, the truth of this judgment and conviction, philosophers assert, cannot be assumed to be valid, but must be vindicated on solid rational grounds, before it can be admitted as a philosophic certainty. After all, these experiences, and the spontaneous convictions based on them, are only the data, the facts, the raw materials, of the problem of knowledge; it is the duty of the epistemologist to investigate whether the ordinary man's interpretation of these facts is the one and only legitimate explanation possible.

And the philosophers are right. The matter is not as obvious as the ordinary man thinks it is. For one thing, many of man's spontaneous convictions have been *proved to be wrong*. The first chapter pointed out a few instances; and there are many others which are clearly wrong or at least of very doubtful validity. That being the case, it is but natural to ask: Are these spontaneous convictions really trustworthy? Might it not be found, on closer examination, that the whole structure of these convictions is without a solid foundation in reason? If some are false, might not the majority of them be false? Since many judgments, to which man gave the firm assent of certitude, were afterwards discovered to contain error and not truth, what test have we to enable us to distinguish between truth and error in our judgments and convictions? Apparently too much importance has been attached to spontaneous convictions.

Here is another consideration: Are these convictions justified when we consider the *nature of knowledge*? Knowledge, after all, is subjectively present in the knower. The cognitive acts are *subjective, intra-mental states* of the knowing subject or Ego. All perceptions, ideas, judgments, inferences, and self-consciousness take place *within* man as the result of his own Cognitive activities. Is not all knowledge, then, purely subjective and intra-mental? And if so, how can we feel so certain that it represents an objective, extra-mental reality at all?

Even if we assume that there exists an objective, extra-mental world which somehow contacts our mind, it would still be a fact that the *mind* of man *actively co-operates in producing knowledge*. The different sense-organs and the

intellect, each with its own proper mode of action, clearly show this. How much of our knowledge, then, is due to the influence of exterior reality and how much to our internal faculties?

Might not this influence of our internal perceptive powers be so subjectively different from the influence of the exterior reality as to completely transform our knowledge? We would have knowledge of reality, of course, but it might not correspond to reality-as-it-is-in-itself. It might thereby become an *idealized* representation of reality, with more of the 'idea' in it and less of the 'reality.' How are we to know?

Many philosophers find a practically insurmountable difficulty in the very notion of the mind knowing the physical world. Ever since René Descartes (1596—1650) injected the idea into philosophy that the essence of the mind is 'thought' and the essence of matter is 'extension' and that there exists an irreconcilable antithesis between the two, the problem of how the mind can possibly contact matter and come to a knowledge of it has been acute. It is certainly not easy to understand how an *un-extended* mind can conform itself to *extended* matter, or how the latter can make a cognitional impression on the former. And if both are such irreconcilable opposites, as Descartes claimed, then each should be a closed entity in itself, incapable of contact with the other. The logical tendency on the part of thinkers will then be to reduce all human knowledge either to a mere perception of the material world (*materialism*) or to a mere system of intellectual thought (*idealism*). And that is what has happened. Others, realizing the inadequate nature of both these extreme theories of knowledge and

desiring to give the spontaneous convictions of man their due, have endeavored seriously to discover a bridge between mind and matter, so as to safeguard the fundamental validity of human knowledge acquired through sense-perception and intellection (realism). The problem is admittedly difficult and deserves deep study.

The *general problem* of knowledge, then, is this: *Have our spontaneous convictions a rational foundation, so that they are based on impressions derived from reality and actually give us knowledge of reality as it is in itself?* Such is the problem of knowledge which we must attempt to solve.

SUMMARY OF CHAPTER III

The facts which form the basis of the problem of knowledge are the spontaneous convictions of the ordinary man, in so far as they are considered by him to convey a genuine knowledge of reality as it is in itself.

1. *Convictions Based on Sense-Perception.* The senses are: sight, taste, smell, hearing, and touch; central sense, imagination, sense-memory, and instinct. All convey knowledge of the physical world in some form or other, and the ordinary man is convinced that things really are as perceived.

2. *Convictions Based on Intellection.* Intellectual knowledge appears in three phases: ideas, judgments, inferences. By means of them, man is certain, the mind possesses a true knowledge of reality.

3. *Classes of Truths.* These are: analytical judgments, containing truths directly evident to the intellect through an analysis of the ideas involved; synthetic judgments, containing truths derived from direct experience; mediate analytical judgments, deduced by inference from first principles; inductive laws and generalizations.

The common characteristic of all spontaneous convictions is: Man's knowledge is a genuine representation of reality as it is in itself.

4. *The Epistemological Problem.* Philosophers admit these convictions as subjective facts, but they contend that these convictions, as interpretations of reality, must be validated. The main reasons are: Many such convictions

have been proved to be wrong. The nature of knowledge is such that cognitive acts are subjective; may not all knowledge be purely subjective? The active cooperation of the mind in the process of knowledge may produce an 'idealized' representation of reality.

The general problem of knowledge, then, is as follows: Have our spontaneous convictions a rational foundation, so that they are based on impressions derived from reality and actually give us knowledge of reality as it is in itself?

1 In the course of this book there will be occasion to speak of these senses again. For the sake of brevity and in deference to usage, the senses just mentioned will be grouped under the common term 'touch.'

Chapter 4

SKEPTICISM AND DESCARTES' DOUBT

IT IS THE PURPOSE OF EPISTEMOLOGY TO TEST THE VALIDITY OF man's spontaneous convictions and see whether they are justifiable before the bar of rational criticism. If they are vindicated after a thorough investigation of their ultimate grounds and causes, they become *reflex* and *philosophic certainties* and will rest upon a firm, scientific basis. If, however, a critical examination should show that these spontaneous convictions are blind assents of the mind or are the result of some compulsory internal mechanism of the human mind, their truth-value will either be disproved or will remain forever in doubt.

In approaching the problem, the *method* employed will be a matter of great importance. A wrong method may produce disastrous results, just as a march from a false starting point, persistently carried on, will take the traveler far away from his goal; not every route will lead to the desired destination. We must never overlook the fact that, while investigating the mind and its faculties, we are using this very mind and its faculties as the instruments of our investigation. On the face of it, this seems an unwarrantable procedure. Since the validity of the mind and its faculties is

at stake, how can their use in this investigation be legitimate? The answer is: the truth of Our whole domain of knowledge being under examination, the only legitimate procedure available is to analyze our knowledge *reflectively* and watch the operations of our mind in the formation of its spontaneous convictions, so as to see whether they are based upon truly rational grounds; there is no other way possible. The only alternative would be to approach the Problem in the *attitude of complete doubt*. The *initial state of mind* would then be to doubt absolutely everything, including the capability of the mind and its faculties to attain to any and all true knowledge. This, of course, would mean to approach the problem of human knowledge with the method of universal skepticism. At first blush, this would seem to be the logical thing to do — doubt everything from the start and then work our way upward toward certitude and truth. But this method would be fatal in its very inception.

HISTORY OF SKEPTICISM

A number of ancients and moderns have defended speculative skepticism. Among the ancients we find *Protagoras* (fifth century B.C.), *Gorgias* the Sophist (contemporary of Protagoras), *Pyrrho* (360—270 B.C.), the real founder of speculative skepticism, *Arcesilaus* (316—241 B.C.), *Carneades* (219—129 B.C.), *Aenesidemus* (first century B.C.), Agrippa (contemporary of Aenesidemus), and *Sextus Empiricus* (about second century A.D.). Agrippa and Sextus Empiricus formulated the reasons for universal

skepticism under five heads: the differences of opinions and theories among men; the necessity of an infinite regress for every demonstration; the subjective and relative character of all perception; the gratuitous assumption of all axioms and principles; the vicious circle, or begging of the question, involved in every syllogism.

Among Christian philosophers universal skepticism never made headway. But the Renaissance, with its blind adoration of everything Grecian, again brought skepticism to the fore. *Michael de Montaigne* (1533—1592) in his *Essais*¹ defended it. Others who followed Montaigne in this trend of thought were *Charron* (1541—1603), *Sanchez* (1562—1632), *Huet* (1632—1721), *Pascal* (1623—1662), *Bayle* (1647—1706), and *Jouffroy* (1796–1841). Some of these were not really skeptics in principle. They attempted to show the constitutional inability of the human mind in its natural powers to arrive at truth, in order to vindicate the necessity of faith in divine revelation. It was a case of faulty apologetics.

Modern skepticism has its most noteworthy representative in *David Hume* (1711—1776). According to Hume, knowledge consists of mere perceptions, and these are twofold in character: impressions, which are the more lively perceptions; and ideas, which are but faint images of impressions. Thought is thus reduced to sense-knowledge. All axioms and principles of science are the result of mere associations of impressions, made by the mind through force of habit; they are, therefore, purely subjective in nature and have no objective value. He considered the arguments of the skeptics to be unassailable. In an indirect

way, Hume's skepticism has exerted a powerful influence on modern thought.

It is obvious that a universal skeptic, who really and seriously doubts or denies the validity of all knowledge, cannot be convinced by any argument which may be advanced against his position: he would be forced to doubt the fact that such an argument has been advanced. He is as isolated in his skepticism as a fly buzzing in a vacuum; if, indeed, a fly can buzz in a vacuum, when both the fly and the vacuum probably are nonexistent. When we argue against skepticism, it is not our purpose to convert the skeptic himself; we intend to show non-skeptics that universal skepticism is folly. In doing so, we achieve a double result: we show directly that universal doubt is an *improper approach* to the problem of knowledge, and we demonstrate indirectly that any system which logically leads to skepticism must be *intrinsically wrong*.

Our contention is that universal skepticism cannot be the proper initial state of mind with which to approach the problem of knowledge, because it is a practical impossibility and a philosophic absurdity.

FALLACY OF UNIVERSAL SKEPTICISM

Skepticism is a *practical impossibility*.

No sane human being can live without certitude of a practical kind. Even the most confirmed skeptic,

no matter how many reasons of a theoretical and speculative nature he may have for doubting the possibility of genuine certitude, cannot lead a human life without

denying his skeptical theory all day long in his *conduct*. His life shows that he is certain of very many things: the physical world, with its seasons and changes of weather, with its periods of day and night, with its differences of time and space relations; his own body, in all its concrete reality, in its conditions of health and sickness, in its physical needs of food, drink, and sleep; the existence and knowability of other people and other minds, some of whom agree with him while others disagree, with whom he communicates by means of conversation and writing, and whom he tries to convince of the truth of universal doubt. The story is told of Pyrrho the Skeptic that, when chased one day by a rabid dog, he ran for safety without allowing his skepticism to exercise its doubt about the existence and viciousness of the brute. When the bystanders laughed at him and ridiculed him for the inconsistency of his action, he is said to have made the sage remark (completely out of keeping with his theory): "It is difficult to get away entirely from human nature." After all, he could not doubt, in an un-theoretical moment, that his body and the dog were real objects.

This discrepancy *between fact and theory*, between life and philosophic system, between practical certitude and speculative doubt, is an incontrovertible proof that universal doubt is an impossibility except as a mere formulation of the mind. When facts and theories clash and contradict each other in such transparent fashion, the sane man will not deny the facts and cling to his theories, but will realize that something is radically wrong with his views. Facts cannot be denied. To persist in universal skepticism in the face of a million contradicting facts of life bespeaks

either insanity or stubbornness of mind. When the inconsistency between life and theory cannot be harmonized, it will not do to deny life, because that would be ridiculous; the theory must be abandoned as essentially faulty. Universal skepticism, therefore, must be rejected as a practical impossibility.

Universal skepticism is also a *theoretical absurdity*.

One simply cannot doubt all things and principles, not even in a speculative way. The skeptics prove this by their own intellectual *inconsistencies*; and inconsistencies are the stigma of every false theory. Any normal person will realize the inherent contradiction of universal skepticism, if it is real and genuine, upon considering the following points.

Skeptics contend that real certitude in knowledge is impossible. so that we must always suspend our judgment because of a real doubt as to the truth of our judgment. This, in their view, is the only logical and rational thing to do. But then, they have at least arrived at this truth that we cannot be certain; and there is at least no doubt that we must doubt. Therefore, even skeptics possess certitude about something, and their fundamental tenet of universal doubt is involved in a contradiction.

Skeptics claim we must suspend our judgment regarding any question, because we might fall into error. But error is the opposite of truth. Consequently, they acknowledge that there is a difference between 'truth' and 'error,' and the two are not the same. Similarly, they must admit that 'certitude' and 'doubt' are not the same; otherwise, why should we doubt rather than be certain? Their very

insistence on this difference shows plainly that they recognize the fact that something cannot be true and erroneous, certain and doubtful, at the same time. But thereby they surreptitiously admit the certainty of the truth of the Principle of Contradiction.

Skeptics either have valid reasons for their universal doubting, or they have no valid reasons for it. If they have valid reasons, they surely know something that is valid, and they no longer are real skeptics. If they have no valid reasons, they have no reason to doubt. In the first case their position is inconsistent, and in the second case their position is irrational. Whichever way they turn, their position is untenable.

Skeptics, in defending the necessity of universal doubt, must naturally be conscious of their doubt and its necessity; for, if they were not conscious of this, they could neither be aware of their doubt nor speak of it. Consequently, they rely upon the *testimony of their consciousness* as a source of valid knowledge. But that involves certitude regarding their own existence and person and regarding the trustworthiness of consciousness. They cannot, in consistency, cast a doubt upon the testimony of consciousness, because the argument of St. Augustine, in speaking to the skeptics, would apply to them: "If I err, I exist. For one, who does not exist, cannot err; and by the very fact that I err, I exist. Since, therefore, I exist, if I err, how can I err about my existence, when it is certain that I exist if I err."² That the skeptic must admit and acknowledge the certain existence of various states of his own consciousness, has been pointed out by St. Augustine in

another passage, marked by a keen appreciation of the facts in the case: "If he doubts, he lives; if he doubts, he remembers why he doubts; if he doubts, he understands that he doubts; if he doubts, he wants to be certain; if he doubts, he thinks; if he doubts, he knows that he does not know; if he doubts, he judges that he must not give a hasty consent."³ Notwithstanding their claim to universal doubt, therefore, the skeptics by their doubting actually, though inconsistently, express certitude concerning a great number of facts and principles. Universal skepticism collapses under the weight of its own folly.

And thus we see that universal skepticism is a philosophic absurdity.

REFUTATION OF SKEPTIC ARGUMENTS

But what about the arguments of the skeptics? Do they not show that valid knowledge is impossible of attainment for the human mind? A close examination will reveal the fact that *the arguments of the skeptics are fallacious*. Some of their contentions have been answered in the preceding paragraphs, and so we will restrict ourselves to those of a more formal and logical character, since they are more pertinent to the present problem.

Conflicting and *erroneous opinions*, they contend, have been held by men on every question that has ever engaged the attention of the human mind. This complete lack of uniformity in their views and the presence of errors in these views proves conclusively that the human mind is constitutionally incapable of knowing truth with certitude.

The answer to this is simple. That many errors exist, due to careless thinking, hasty conclusions, faulty education, and lack of observation, is true enough. But this would militate against the possibility of certitude only if the mind were *congenitally* unable to detect and correct its errors of judgment. This is not the case; otherwise we could never change our views with the *consciousness that we have been in error*. The very fact that we recognize error as error (even the skeptics are constantly pointing out errors), is a sure indication that the human mind possesses a criterion or test whereby to distinguish truth from error. All that is required, then, is to be careful in our investigation and apply this test with greater accuracy. That we cannot eliminate all errors is simply due to the limitations of our intellectual powers, but not to the essential inability of our mind to discover and recognize truth. Error is thus accidental, but not essential, to the human mind.

Sextus Empiricus formulated an argument somewhat along the following lines. Whoever thinks he has acquired a knowledge about something with certitude, can have acquired it only in one of three ways: either he proves his judgment by a proof which needs another proof, and this second needs a third proof, and this third needs another, and so on, without ever arriving at a final proof; or he stops at a certain proof, which he does not prove in turn, but simply assumes to be true without proof of any kind; or he proves his statement by some principle, and then later on proves this last principle by his original statement. In the first instance he is guilty of an *infinite regress*, which cannot prove anything, because one can never come down

to the final proof; in the second instance he is guilty of a *gratuitous assumption* which leaves the final proof open to the question of truth or error, thereby settling nothing; and in the third instance he is guilty of a *vicious circle*, and a vicious circle proves nothing at all. This seems a rather formidable argument in favor of universal skepticism. Unfortunately, one other alternative was omitted and that a vital one. Some proofs do not need a subsequent proof to establish their truth and certainty. There are truths which are so self-evident to the mind, that their validity is perceived by an act of *immediate intuition* and demands no further demonstration. That 'I am writing at this moment' is a truth so obvious to me that I need not look for any deep philosophic or scientific proof to give this judgment validity: I simply experience the fact, and that is all there is to the matter; no argument of the skeptics can invalidate this fact for me, because it is self-evident. I am guilty neither of an infinite regress, nor of a gratuitous assumption, nor of a vicious circle, in making this true statement of fact. Incidentally, if the above argument of the skeptics were true, then their argument itself would be invalid for the very reasons which they adduce; and since it is a false argument (according to their own principles), it cannot prove anything in favor of skepticism. The fact, however, that skeptics consider it a true and valid argument, proves that they do consider some knowledge true and valid; and that is just one more example of their inconsistency.

The main argument of *Montaigne* was that an infinite regress would be necessary for every demonstration. He, too, overlooked the fact that first principles are self-evident

and need no demonstration. That $2 + 2 = 4$ is clear by a simple analysis of the ideas involved.

DESCARTES' METHODIC DOUBT

René Descartes (1596—1650) is responsible for the predominance of the problem of human knowledge in modern philosophy. Many of the systems of philosophy and theories of knowledge which have arisen in the last three centuries can trace their lineage directly to the influence of the questions Descartes raised and the method he employed in answering them. He promulgated the principle of 'science without presuppositions' and thereby introduced a new epoch in science and philosophy. It will, therefore, not be amiss to analyze his fundamental ideas and evaluate his method.

As his starting point Descartes begins with the contention that we rely entirely too much on traditional doctrines and spontaneous convictions, so that our supposed knowledge of truth rests mostly on unproved presuppositions. This makes it difficult for us to distinguish between truth and error, since we do not know what is true knowledge and what is unwarranted belief. Hence, he would tear down the whole edifice of knowledge and rebuild it from the foundation, and he would not begin to build until he had reached the one and ultimate truth which was the bedrock of human knowledge. Being a mathematician, he felt convinced that he could deduce all truth from a single fundamental principle. As the instrument of his search for truth he used a *universal*

methodic doubt. His own words will best reveal his line of thought.

“I. In order to seek truth, it is necessary once in the course of our life, to doubt, as far as possible, of all things.

“As we were at one time children, and as we formed various judgments regarding the objects presented to our senses, when yet we had not the entire use of our reason, numerous prejudices stand in the way of our arriving at the knowledge of truth; and of these it seems impossible for us to rid ourselves, unless we undertake, once in our lifetime, to doubt of all those things in which we may discover even the smallest suspicion of uncertainty.

“II. We ought also to consider as false all that is doubtful.

“Moreover, it will be useful likewise to esteem as false the things of which we shall be able to doubt, that we may with greater clearness discover what possesses most certainty and is easiest to know.

“III. We ought not meanwhile to make use of doubt in the conduct of life. .

“IV. Why we may doubt of sensible things.

“Accordingly, since we now only design to apply ourselves to the investigation of truth, we will doubt,

first, whether of all the things that have ever fallen under our senses, or which we have ever imagined, any one really exists; in the first place, because we know by experience that the senses sometimes err, and it would be imprudent to trust too much to what has even once deceived us; secondly, because in dreams we perpetually seem to perceive or imagine innumerable objects which have no existence. And to one who has thus resolved upon a

general doubt, there appear no marks by which he can with certainty distinguish sleep from the waking state.

“V. Why we may also doubt of mathematical demonstrations.

“We will also doubt of the other things we have before held as most certain, even of the demonstrations of mathematics, and of their principles which we have hitherto deemed self-evident; in the first place, because we have sometimes seen men fall into error in such matters, and admit as absolutely certain and self-evident what to us appeared false, but chiefly because we have learned that God who created us is all- powerful; for we do not yet know whether perhaps it was His will to create us so that we are always deceived, even in the things we know best: since this does not appear more impossible than our being occasionally deceived, which, however, as observation teaches us, is the case. And if we suppose that an all- powerful God is not the author of our being, and that we exist of ourselves or by some other means, still, the less powerful we suppose our author to be, the greater reason will we have for believing that we are not so perfect as that we may not be continually deceived.

“VII. We cannot doubt of our existence while we doubt, and this is the first knowledge we acquire when we philosophize in order.

“While we thus reject all of which we can entertain the smallest doubt, and even imagine that it is false, we easily indeed suppose that there is neither God, nor sky, nor bodies, and that we ourselves have neither hands nor feet, nor, finally, a body; but we cannot in the same way suppose

that we are not while we doubt of the truth of these things; for there is a repugnance in conceiving that what thinks does not exist at the very moment when it thinks. Accordingly, the knowledge, '*I think, therefore I am*,' is the first and most certain that occurs to one who philosophizes orderly."⁴

This is indeed a most radical procedure, a veritable revolution of method. Descartes applies the method of universal doubt to 'all things,' attempting to empty the mind completely of all traditional views, preconceived ideas, and spontaneous convictions without exception. Nothing is allowed to remain, no matter how seemingly clear and evident. Even the simplest arithmetical and geometrical problem is not permitted to stand, like ' $2 + 3 = 5$ ' and 'A square has but four sides.' As he expresses himself: "How do I know that I am not also deceived each time I add together two and three, or number the sides of a square, or form some judgment still more simple, if more simple indeed can be imagined?"⁵ Not only the whole physical world, our own body, sense-perception, and the internal states of our consciousness, are thus drawn into universal doubt,⁶ but also the *trustworthiness of our cognitive faculties* and the fundamental laws of thinking, like the Principle of Sufficient Reason and the Principle of Contradiction. This is a most important feature of his method that must not be overlooked.

Descartes' universal methodic doubt is not merely simulated for the sake of an unprejudiced search after truth; it is a real, genuine doubt. "As I desired to give my attention solely to the search after truth, I thought . . . that I

ought to reject as absolutely false all in regard to which I could suppose the least ground for doubt, in order to ascertain whether after that there remained ought in my belief that was wholly indubitable."⁷ Mark the words: "to reject as *absolutely false*." He does not intend to hold his mind in a state of suspended judgment, or merely to leave his spontaneous convictions aside for the time being, in order to investigate their possible validity, which would be *methodic doubt* as generally understood; he is convinced that he ought 'to reject them as absolutely false,' and he actually carries out his plan, so that he really rejects everything down to the one indubitable fact: '*Cogito, ergo sum* - I think, therefore I exist.' This is more than mere doubt, because a doubt presupposes a suspended judgment due to the absence of all reasons for and against a proposition (negative doubt) or reasons of more or less equal value for and against it (positive doubt). Descartes "supposes, for a time, that all these opinions are entirely false and imaginary,"⁸ and he "will continue always in this track until he shall find something that is certain, or at least, if he can do nothing more, until he shall know with certainty that there is nothing certain."⁹ He assumes the attitude that all spontaneous convictions and laws of thought are *errors*.

It makes little difference whether Descartes could and did, actually and really, doubt everything without exception; or whether he merely thought he could and did. The fact is, he did thus doubt everything in principle. He was, of course, not a skeptic, since his purpose was to arrive at the ultimate base of certainty and truth and to rebuild on this

indubitable foundation the edifice of knowledge. He compared himself to Archimedes. "Archimedes, that he might transport the entire globe from the place it occupied to another, demanded only a point that was firm and immovable; so also, I shall be entitled to entertain the highest expectations, if I am fortunate enough to discover only one thing that is certain and indubitable."¹⁰ Descartes was fortunate enough to discover his firm and immovable fulcrum: his own existence — 'I think, therefore I am.' He had now his fulcrum; what would be his lever?

It would have to be the *trustworthiness of his reasoning powers*. But how could he establish this, seeing that this also was involved in universal doubt and destroyed with all other spontaneous convictions? Descartes hit upon an ingenious idea. He would demonstrate the existence of an infinitely perfect Being, who must have given man faculties which are trustworthy and capable of discovering truth. The only thing absolutely certain so far for Descartes was his own existence; and from this fact alone he would be obliged to deduce God's existence.

Here is his line of thought. We have in our mind the idea of God as an infinitely perfect Being. But an infinitely perfect Being must have existence, otherwise it would not be infinitely perfect Ergo, God exists.¹¹ This is an *a priori or ontological argument*. [St. Anselm's *ed.*] Descartes attempts to prove God's existence a posteriori, by means of an argument from causality. We have the idea of God in our mind. Since this idea represents an infinitely perfect Being, we, as finite beings, cannot have originated such an idea in virtue of our own powers. This idea being beyond our

mental capacity, it could have originated only from a Being who possesses such infinite perfection. Ergo, God exists.’¹²

Having proved to his own satisfaction that God exists, Descartes proceeds to show that He is the creator of man.¹³ But the infinitely perfect God cannot be a deceiver; consequently, He cannot have given man deceptive powers of knowledge, and man’s faculties are thus shown to be *trustworthy*, “provided we separate what there is of clear and distinct in the knowledge from what is obscure and confused.”¹⁴ In the light of this criterion of ‘clear and distinct’ knowledge all previous doubts about the world, sense-perception, and intellection must vanish. Skepticism is defeated, and valid knowledge is possible.

FAILURE OF DESCARTES’ METHOD

Descartes’ fundamental purpose was laudable; he desired to defend human knowledge against the attacks of skeptics. Generally speaking, he was justified in demanding that the investigation into the nature and limits of knowledge exclude preconceived ideas, traditional doctrines, and unwarranted presuppositions as evidence and proof, since the validity of all spontaneous convictions was at stake. But when he proposed to approach the problem in an attitude of universal real doubt, discarding even the capability of the human mind to know truth and refusing to accept such essential principles as the Principle of Contradiction and the Principle of Sufficient Reason, he made the solution of the problem impossible for himself. Here are a few considerations which compel us to reject his system.

Descartes began his inquiry by doubting all knowledge without exception; he was even willing to accept it as 'entirely *false*.' This being the case, what about the *idea of God* as an all-perfect Being, since he admits that he discovered this idea in his own mind? According to his own principle of universal doubt, he simply *cannot know* whether this idea of God is correct or incorrect; as a matter of fact, according to this principle, he should consider it as 'entirely false,' until proved otherwise. But if his idea of God as an all-perfect Being may be incorrect, he cannot logically deduce from this idea God's existence and veracity. Since the very idea of God is doubtful, these other things must remain doubtful, and the trustworthiness of man's faculties must also remain doubtful. Descartes cannot escape his own real doubt.

Irrespective of the intrinsic value of the proofs with which Descartes attempts to demonstrate God's existence, we must not overlook the fact that he uses a *process of reasoning* to make this demonstration. Since his very reason and the process of reasoning is as yet of doubtful validity, how can he validly demonstrate God's existence and veracity? The trustworthiness of Descartes' reasoning powers is supposed to flow as a necessary *consequence* from the infinite perfection of God; and God's infinite perfection is made certain to him by means of a proof developed by these very reasoning powers, *before* he has proved that these reasoning powers are valid and trustworthy: he thereby gratuitously *assumes* the very thing *beforehand* which he intends to prove *afterwards*. He unconsciously accepts the trustworthiness of his faculties in

attempting to demonstrate the existence and infinite perfection of God, and that is an illegitimate procedure; because a doubtfully valid faculty can produce only a doubtfully valid argument, and a doubtfully valid argument can only lead to a doubtfully valid conclusion. The whole argument for God's existence and veracity is thus nullified by his doubtful reason and reasoning process; and, since he proves the reliability of his reason and reasoning process by means of God's veracity, which (according to his supposition) must be doubtful, the proof for the trustworthiness of his own powers is nullified and can never be established beyond doubt. His attempt, therefore, to vindicate the validity of human knowledge failed essentially, because, by rejecting the reliability of his own powers to discover and know truth, he made it impossible for himself to extricate himself from the net of his own universal doubt.

Moreover, there are *glaring inconsistencies* in his procedure. He claims to reject everything, even the Principle of Contradiction and the Principle of Sufficient Reason. But he does not. He surreptitiously *assumes the truth* of these principles and uses them continually. As obvious a fact as the '*Cogito, ergo sum*' is really based on the validity and truth of the Principle of Contradiction. This principle asserts that it is impossible for something to be and not to be at the same time. Descartes becomes certain of his own existence by the very fact of his 'thinking' or 'doubting.' True. But why? Because he perceives clearly that it is impossible to 'think and not think,' to 'exist and not exist' at the same time. If Descartes were consistent and really doubted the Principle of Contradiction, he would have

to affirm that *it could be possible* for a being to 'think and not think,' to 'exist and not exist' at the same time. But then, according to his own supposition, he could not be sure after all that the ultimate fact of his existence is certain, and his famous '*Cogito, ergo sum*' has no real objective value. Only by granting the validity and truth of the Principle of Contradiction beforehand, can his existence be established as an objective fact; and that is exactly, though inconsistently, what Descartes does.

The same line of reasoning applies to his *proofs for God's existence* and infinite perfection. Notwithstanding his proofs, his rejection of the Principle of Contradiction will forever invalidate his arguments, because, as long as this principle is not established and accepted, he could never be sure whether it would not be possible for God to 'exist and not exist,' to 'be infinitely perfect and not infinitely perfect' at the same time. Similarly, he would always be compelled to remain in doubt whether God could not be 'veracious and not veracious,' 'deceiving and not deceiving,' unless the Principle of Contradiction were taken as granted *before he begins to prove God's existence*. Unwittingly Descartes does accept this Principle of Contradiction throughout his demonstrations, but that is an inexcusable inconsistency.

So, too, Descartes conducts his inquiry under the supposition that he has doubted the Principle of Sufficient Reason and the Principle of Causality. But he does not hesitate to use these principles *before he has established their validity*. Consider his a posteriori argument for the existence and infinite perfection of God. He contends that the idea of God as an all-perfect Being could not have

originated in our mind, because such an idea would exceed the causality of the human mind, the latter being less perfect than the contents of the idea itself; consequently, this idea had to be produced in us by God Himself (and this proves that God exists as an infinitely perfect Being), otherwise there would be no sufficient reason for the presence of such an idea in our mind. This line of reasoning shows plainly that Descartes uses the Principles of Sufficient Reason and Causality in demonstrating God's existence, *although he doubts their validity*. Now, if he lets these principles stand as doubtful, his entire demonstration is vitiated and nullified by doubt; and if he accepts them as valid prior to establishing their validity, he acts contrary to his fundamental doubt and is inconsistent: in either case he makes the demonstration of God's existence impossible. His actual procedure in all the arguments he makes is such, however, that he presupposes the validity of these laws of thought; and that is for him a glaring inconsistency, since his universal methodic doubt will not permit him to accept their validity before he has proved the existence and veracity of God.

Finally, Descartes' universal methodic doubt *leads logically to universal skepticism*. No certitude can ever be attained in a system where the very foundations of human reason are completely destroyed. When he rejects as doubtful and even as 'absolutely false' all in regard to which he could imagine the least ground for doubt (*absolument faux tout ce en quoi je pourrais imaginer la moindre doute*), he saws off the very limb upon which he is seated. If the nature of his mind and the laws of thought are called into

real doubt (not to speak of considering them to be 'absolutely false'), then all acts and facts of consciousness, all ideas, judgments, and inferences, can no longer be trusted. But how can the mind attempt to validate its own trustworthiness except by means of these things? If Descartes mistrusts the simple judgments ' $2 + 3 = 5$ ' and 'A square has four sides,' how can he trust his faculties in making the far more complicated arguments with which he tries to prove God's existence and infinite perfections?

The effort of Descartes to find his way back to certitude by means of the roundabout detour of the existence and veracity of God, shows the desperate plight in which he had placed himself by his universal doubt. The steps he takes in retracing his way are these: his own existence; the existence and infinite perfection of God; God's absolute veracity; his creation by God; the trustworthiness of his faculties, due to the veracity of God who created him; the truth and validity of all those spontaneous convictions of his mind which are 'clear and distinct.' But we have seen that Descartes could not consistently prove God's existence, since he could only do so by means of a reasoning process which, according to his own principles, was essentially doubtful in its validity, and even 'absolutely false.' The only thing of which he could ever be certain was his own existence; and this, too, strictly speaking, Descartes should have doubted, because he had doubted the Principle of Contradiction and the testimony of his own consciousness. Our modern Archimedes had indeed found his fulcrum, namely his own existence; but now he could not move the world, because he had thrown away his lever.

Descartes, if he had been consistent, should have embraced universal skepticism, because his universal doubt left him no other choice: he had no way of retracing his course. He was like a mariner who scuttles his boat and swims to a rock in mid-ocean. The rock is the solitary fact of his own existence. True, he had found a solid point. But it is a lonely and desolate spot; and he is marooned on it forever, doomed to die of mental starvation, surrounded by an unbridgeable ocean of doubt.

The Cartesian universal methodic doubt, therefore, is not a proper approach to the problem of human knowledge. It is in reality only a variation of universal skepticism, and as such it is absurd. We will have to make our approach in a different fashion.

The necessary conclusion to be drawn from the above critical examination of universal skepticism is obvious: *Complete doubt cannot be the proper approach to the problem of human knowledge.* It would be fatal. Starting with complete doubt, we can no more reach a solution of the problem of human knowledge than a bird can fly with amputated wings.

Another important conclusion is this: *Any theory of knowledge which leads logically to universal skepticism is intrinsically false.* Nothing could be plainer. There must be an essential flaw in a theory which, if consistently carried out to its logical conclusions, ends in the absurdity of skepticism. This principle will enable us to pass a condemnatory verdict on many systems of thought, even though we may not always be capable of discovering the exact fallacy underlying the systems.

SUMMARY OF CHAPTER IV

In making a critical examination of the spontaneous convictions of man, improper methods of approach must be avoided. Such are universal skepticism and Descartes' universal methodic doubt.

1. *Skepticism a False Method.* It is a practical impossibility. No sane man can live without many practical certainties, denying his theoretical skepticism in his daily conduct. It is also a theoretical absurdity, because it is full of inconsistencies. Skeptics are 'certain' that we must doubt. They distinguish between 'truth' and 'error,' 'certitude' and 'doubt,' realizing that these opposites cannot be identical; thereby they admit the validity of the Principle of Contradiction. They give reasons for skepticism which they consider cogent and valid, contrary to their skeptic principles. They are conscious of their doubts; they thus accept consciousness as a valid source of knowledge.

2. *Refutation of Skeptic Arguments.* Erroneous opinions do not prove that certitude is impossible; errors are accidental, because we can detect and correct them. It is not true that every argument involves either an infinite regress or a gratuitous assumption or a vicious circle; self-evident truths avoid all these logical difficulties and form the ultimate basis of knowledge.

3. *Descartes' Methodic Doubt.* In his endeavor to place knowledge upon a firm basis, Descartes sought for an indubitable truth as his starting point, doubting everything in the meantime. He found this truth in the fact of his own

existence. He then deduced God's existence from his idea of God. God, being infinitely perfect, cannot deceive; consequently, He must have given man trustworthy faculties. Man's faculties having been proved to be trustworthy, man can now acquire true and valid knowledge.

4. *Failure of Descartes' Method.* Since he doubts everything, he cannot be certain that his idea of God is correct. He uses a reasoning process to demonstrate God's existence; but his reason is of doubtful value, until he proves its trustworthiness from the veracity of God. He is guilty of inconsistency, in as much as he presupposes the validity of the Principles of Contradiction, Sufficient Reason, and Causality, although their validity has not been established by him. His procedure, if consistently carried through, would lead logically to universal skepticism.

Conclusions to be drawn: complete doubt cannot be the proper approach to the problem of human knowledge; any theory of knowledge which leads logically to universal skepticism is intrinsically false.

Chapter 5

THE PRIMARY TRUTHS

THE PROPER APPROACH TO THE PROBLEM OF HUMAN KNOWLEDGE IS an important matter. Since universal skepticism would produce a paralysis of our reasoning powers, any initial attitude of mind which would involve skepticism must be excluded as wrong from the beginning. For this reason Descartes' methodic doubt, because it was intended by him as a real and genuine doubt about everything without exception prior to all investigation, was doomed to failure: it could lead only to skepticism, if consistently carried out. Such attempts, however, have done this much good, that they show us certain pitfalls which must be avoided. We are now better able to understand the *proper attitude* which is required in our approach to the problem.

The proper approach must be determined by the *purpose* of the whole investigation, and the purpose of epistemology is neither more nor less than this: to inquire into the rational grounds and ultimate reasons of our spontaneous convictions by means of a critical examination, in order to see whether these spontaneous convictions are *justifiable before reason* and can thus become philosophic certainties. This entails a number of things.

INITIAL STATE OF MIND

For one thing, we must accept the *data of the problem*, at least in so far as they are subjective facts in our mental life. This includes the entire body of spontaneous convictions as outlined in previous chapters. Whatever may be the outcome of our investigation, we cannot deny that we actually have these convictions. These convictions, then, must be accepted as the raw materials upon which our reason must work in attempting to solve the problem in question.

Again, it must be borne in mind from the start that the purpose of epistemology is not to discredit and disprove our spontaneous convictions. If anything, its purpose is rather the opposite — to prove and *vindicate* them. This does not mean that the philosopher should not investigate their claims in all critical severity; that is both his right and his duty. But the fact is, as we pointed out in the first chapter, that these convictions have a strong *prima facie evidence* in their favor, since they are spontaneous and natural and are in agreement with the facts of our whole *ordinary life*. In the research work of any of the sciences this would be considered sufficient proof for a well-grounded *hypothesis*, and we should also, therefore, accept the validity of these spontaneous convictions as *hypothetically true*. As a consequence of this, only proofs and reasons of the most serious nature should compel us to recede from this position.

Furthermore, it must be obvious that we cannot take up the single spontaneous convictions present in our mind and

investigate them individually. This would be a hopeless task. They are far too numerous and detailed, comprising the whole field of knowledge contained in the various sciences and in our ordinary life. It will be more advantageous to group them into *broad classes* and submit these classes to a critical examination; the individual convictions will then stand or fall with their respective class as a whole. If, for instance, we can prove that our senses are valid sources of knowledge, then our convictions based on sense-perception will be valid as *a class*; and that would be sufficient to show that these have a rational foundation.

Finally, we cannot begin our critical inquiry by really doubting everything, since that would be universal skepticism, and skepticism, as we have seen, is irrational; consequently, *we must begin by accepting something as certain*. On the other hand, we cannot begin with unwarranted presuppositions, because, by the very fact that they are unwarranted, they would be of doubtful validity, and thus our entire investigation would rest upon a doubtful foundation. How can this initial difficulty be overcome?

There is only one way in which this can be done: We must begin with some truths which will be so transparently clear and *irresistibly evident* to our reason that a little reflection will give us *reflex* and *philosophic certitude*. In this way we will be guilty neither of skepticism nor of *unwarranted* presuppositions; the fact that they are certain excludes skepticism, and the fact that they are irresistibly evident to our reason saves them from being unwarranted presuppositions. Certitude, as we know, is the state of the

mind in which it gives a firm assent to a judgment without fear of the possibility of error, due to recognized valid reasons. If we were to give such an assent to a judgment without recognizing any valid reason for this assent, then indeed we would have an unwarranted presupposition; we would simply presuppose it to be true without knowing why, and that would be unwarranted. But if we understand the ground or reasons which exclude all reasonable fear of error, then our assent to such a judgment would be warranted and *rationally justified*. Hence, if we could find some such *basic truths*, we would have a solid footing for our inquiry and proceed from there in the investigation of our spontaneous convictions. Are there any such truths?

There are; many of them. At present, however, we are only concerned with those which are *essential to all valid knowledge* without exception. There must be some truths which form the bedrock of all knowledge, which lie at the bottom of all thinking, and which constitute the indispensable foundation of all reasoning. These truths, which must be present in every act of knowledge, we must establish and vindicate first, before we can safely investigate the various classes of spontaneous convictions. With a little thoughtful reflection we will perceive that there are *three primary truths* which are most fundamental to the human mind and absolutely necessary in all its operations:

The First Fact: my own existence — ‘I exist.’ *The First principle*: the Principle of Contradiction — ‘It is impossible for something to be and not to be at the same time.’ *The First Condition*: the essential trustworthiness of my reason — ‘My reason is capable of knowing truth’

These three primary truths are, of course, spontaneous convictions of our mind, and as such they are accepted without question and never doubted by the ordinary man. That he is convinced of his own existence goes without saying. That he is convinced of the truth and validity of the Principle of Contradiction, is equally certain. He may not be able to formulate the principle in words; but that the *meaning* of this principle well known to him and accepted in all its rigor, cannot be doubted. He shows it in all his thinking and reasoning. It is contained *implicitly* in all his statements. When he says 'I am not feeling well,' he is conscious of the fact that it is impossible to 'feel well' and 'feel ill' at the same time. And when he says 'You are wrong,' he realizes that one cannot be 'right' and 'wrong' in the same way at the same moment. And so with other judgments; they all involve the Principle of Contradiction. The same is true of the essential reliability of his reason. He is conscious, of course, that he can and does make many errors of judgment; but he is also conscious of the fact that these errors are only incidental and do not invalidate the *essential* capability of his reason to know truth and to distinguish it from error. The ordinary man, whether educated or uneducated, once he is aware of the full grounds underlying the subject in question and can say 'I understand this,' never doubts that his knowledge is true and valid. Man's daily life in all its phases is regulated by his spontaneous conviction of the validity of these primary truths.

PROOF OF THREE PRIMARY TRUTHS

This brings us face to face with the vital question: Must we then accept these primary truths without demonstration or proof? Without demonstration, yes; without proof, no. We must be clear in our own mind what we understand by 'demonstration' and 'proof.' A 'demonstration' is a *mediate inference*, a process of reasoning, by means of which, from something that is better known, we conclude to the truth of something that is less well known. A 'proof' is anything that makes the truth of a thing indubitably clear to our mind, whether this be by means of a demonstration proper or by means of an immediate insight into the truth due to the *irresistible clearness of the truth itself*. In the latter case (immediate insight based on self-evidence) a 'demonstration' will be superfluous, because the truth is clear in itself and does not need a clearer truth to demonstrate it; it is only when something is not clear in itself that a 'demonstration' becomes necessary to prove its truth. Bearing this distinction in mind, the answer to the question is as follows:

The three primary truths cannot be demonstrated; nor do they need a demonstration, because they are self-evident.

They cannot be demonstrated. The only way I could possibly demonstrate my own existence would be by deducing it from some other idea more clear to me than my existence itself. But what can be clearer to me than my own existence? The only imaginable way would be to deduce it from my thinking, my willing, or some other operation of

mine. But these operations presuppose and include my existence. Such a demonstration could not be formulated except in the following manner: 'Everyone who thinks, exists; I think; ergo, I exist.' The major premise is a general truth; well and good. The minor premise, however, expresses a fact, 'I think.' This minor premise is really nothing else than 'I am one who thinks,' and 'I am' is the same as 'I exist.' Consequently, my existence is already contained in my premise directly, and that is a begging of the question. The demonstration is invalid, because the minor premise, since it already involves my existence, is not really clearer to me than my existence, which I intend to demonstrate. Hence, I cannot demonstrate my own existence.

Nor can I demonstrate the *Principle of Contradiction*. Any demonstration which I might use to prove it, would have to consist of premises which are true and not erroneous, in order to be a valid demonstration. But to be 'true and not erroneous presupposes that I know that 'truth' and 'error' are not, and cannot, be the same. That, however, again presupposes and involves the truth of the Principle of Contradiction, namely that 'it is impossible for a thing to be and not to be at the same time.' Again, such a demonstration would have to possess consistency, in order to be valid. But that implies that 'consistency' and 'inconsistency' are opposed and cannot be the same; and that is due to the Principle of Contradiction. Hence, the truth of the Principle of Contradiction cannot be demonstrated, but must be presupposed for the validity of every demonstration.

Similarly, I cannot demonstrate the *reliability* of my own reason. I could only attempt such a demonstration by formulating an argument *with my own reason*. But this very attempt at a demonstration by means of my own reason *presupposes* that my reason is really reliable and capable of making a valid demonstration. The trustworthiness of my reason would thus already be presupposed and involved in the demonstration itself, and that would make the demonstration invalid.

Any attempt, therefore, to prove the three primary truths by means of a real demonstration can amount to nothing more than a begging of the question. Does that mean that they are *gratuitous* assumptions, *unwarranted* presuppositions? If that were the case, then our knowledge would indeed be grounded on an irrational foundation. We must remember, however, that only those truths demand a demonstration which are so obscure in themselves or so doubtful to our mind that we need another and clearer idea to manifest them to us. If they are perfectly clear and self-evident, we do not need a demonstration to make them clear, because the very purpose of a demonstration is already fulfilled. Under such circumstances, therefore, a truth would not be a gratuitous assumption nor an unwarranted presupposition. And that, precisely, is the case with the three primary truths: they need no demonstration, because *they are self-evident*.

Consider the First Fact — ‘I exist.’ The truth of my own existence is so evident to me that I am compelled by irresistible necessity to accept it, because I have a *direct insight* and an *immediate intuition* of myself as existing. I

could not doubt this fact, even if I tried. The very doubt or denial of my existence would prove my existence, since I could not 'doubt' or 'deny,' if I did not exist. Why, then, should I demand or need a demonstration of this perfectly obvious fact? It would be unreasonable to demonstrate something which is clearer to me than any demonstration.

The same applies to the First Principle; it requires no demonstration, because it is intuitively clear to the mind and certain beyond doubt and denial. No one can doubt or deny the validity of the Principle of Contradiction without asserting its validity by his very doubt or denial. If he actually denied or doubted it, he would by this fact alone affirm that 'truth' and 'error,' 'doubt' and 'certitude' are not, and cannot be, the same. And why are they not the same? Because of the validity of the very Principle of Contradiction which he doubts or denies. Since it is the Principle of Contradiction alone which guarantees the validity of every demonstration, and no demonstration can be valid without it, it is evident that no demonstration can give validity to the First Principle itself; the First Principle is so obvious and clear to the thinking mind, that the mind needs no demonstration to make it clear.

And so it is with the *First Condition*. It needs no demonstration to manifest its truth, since not only every argument in its favor presupposes the reliability of our reason, but every doubt or denial does the same. By the very fact that I would doubt or deny the trustworthiness of my reason, I would take it for granted that *my reason is reliable and trustworthy in its doubt or denial*, since I thereby affirm that I understand clearly the difference

between truth and error and also the objective value of the reasons or grounds which should govern my assent. Even the skeptic thinks that he is right in doubting everything, because of the many proofs he has discovered against certainty; but thereby he asserts indirectly that his own reason is reliable in its investigation. When, therefore, a thing is so clear and evident that I cannot doubt or deny it without affirming it by my very doubt or denial, I need no demonstration to prove its truth and validity.

After all, clearness of insight due to the *evidence of truth itself* is the basis of knowledge for our mind. When the analysis of a judgment does not make its truth clear to us, then we must have recourse to a demonstration, in order to obtain the necessary clearness of insight into its truth; if the demonstration gives our mind this insight and convinces it, it is simply because it has made *truth evident* to the mind. When, however, our mind obtains this insight into truth by a mere analysis and contemplation of the judgment, due to the irresistible evidence of the truth itself without the aid of a demonstration, then we have truth and certainty in its purest, simplest, and *most rational* form. Such is the truth and certainty of the three primary truths as just shown.

We see, then, that the three primary truths are not unwarranted assumptions and presuppositions. They are eminently rational and philosophically well grounded. Our assent to their truth is based on undeniable and unshakable evidence of the most convincing nature and not upon some blind and unaccountable compulsion of our mental constitution. This being the case, the First Fact, the First Principle, and the First Condition are no longer only the

spontaneous convictions which we share with the ordinary man, but *reflex* and *philosophic certainties* which have stood the test of our critical examination. They form the foundation of all knowledge, science, and philosophy. With these three primary truths critically established and philosophically certain, our investigation of the problem of human knowledge has been placed upon a solid basis, and we can now proceed with confidence and definite hope of success.

CRITICAL DOGMATISM

The primary truths being *rational presuppositions*, which must be accepted without positive demonstration (which, of course, they do not need, as we have shown), and which are considered prerequisites for every process of thinking and reasoning, are styled *dogmas of epistemology*. The system of epistemology which, after a critical examination of their validity, accepts these three primary truths as essentially necessary for every process of thinking and reasoning prior to the investigation of the various classes of spontaneous convictions themselves, is called *critical dogmatism*. We are, therefore, critical dogmatists. That these 'dogmas' are not to be confounded with the dogmas of theology is evident. The term is derived from the Greek word *δόγμα* and means any accepted doctrine or tenet. Here, of course, it is taken in a philosophical sense.

Critical dogmatism, then, is the only logical and rational approach to the problem of human knowledge. We must accept it, if we do not wish to be caught in the inescapable

net of universal doubt. Universal doubt, as an initial state of mind in approaching the problem, would mean the paralysis of all thought, the bankruptcy of science, the suicide of reason; it would condemn us to failure before ever we started. The only alternative is critical dogmatism.

D. Card. Mercier, together with other neo-scholastics of the Louvain School, objects strongly to the acceptance of these three primary truths or 'dogmas.' He considers this an 'exaggerated dogmatism.' Here is his attitude in the question:

"These supposed primary truths, if we except the principle of contradiction, are not so self-evident as to call for no proof. If they do not demand demonstration in the strict sense of the word, yet certainly an attentive examination is necessary to bring out their evidence. Especially does the capability of the mind to know the truth need consideration, if not actual demonstration, for is it not the very subject of this treatise? To affirm it *a priori* is to ignore the problem of certitude instead of solving it.

"We can, then, assert *a priori* neither the essential incapability of the human reason (universal doubt) nor its general *capability* to know the truth (exaggerated dogmatism). Between these two extreme theories there is room for an intermediate one which we adopt as our own, one which we shall call mitigated or rational dogmatism. It may be stated thus:

"1. As regards the capability of our *faculties* or powers of acquiring knowledge, mitigated dogmatism *deliberately abstains* from making a judgment, holding that at the beginning of the study of the problem of certitude it is

impossible either to affirm or to deny our mental capability of knowing truth. Before a judgment can be pronounced we must first study the value of the mind's acts. The first and immediate subject for our reflection is not the power as such but the acts, from which alone we come to a knowledge of the nature of the faculty that elicits them. If by dint of reflection we can discover that our mental acts, our assents, are objective, that is, conformable to things as they are in reality, then and then only shall we be able legitimately to infer that our mind is capable of attaining true knowledge. After all, this manner of procedure is a truly scientific method based upon observation: to use a homely comparison, a good digestion is the only proof of the stomach's ability to digest properly.

"2. As regards our judgments or the *acts* of the mind by which truth is attained, the initial state of the intelligence at the outset of the study of epistemology differs according as these judgments are mediately or *immediately* evident. In the case of the former, *doubt* cannot be avoided, whilst in that of the latter, which stand firm against any doubt, a state of certitude is always present."

He then goes on to show that these mediate judgments must be demonstrated, until they finally rest upon evident, indemonstrable propositions. And he concludes his exposition with the words:

"Sooner or later, then, the demonstration of mediate propositions leads us back to indemonstrable premises which we call *immediate propositions*: such are all propositions in which the identity or the nonidentity of the predicate with the subject is seen by the simple comparison

of the terms. These immediate propositions, although indemonstrable, are by no means doubtful: their very evidence makes them indemonstrable, that is to say, incapable of being referred to propositions which are more evident. And when they are reflected upon by the mind, they necessarily draw its assent, *they force their truth upon the mind*.

“In setting out to solve the problem of certitude we therefore suppose only two facts, which skeptics themselves are willing to admit, namely, the existence of necessary spontaneous assents and the power to examine these by reflection. To disallow these data would make the problem of certitude impossible, inasmuch as to suppress ‘*id de quo quaeritur*’ necessarily involves the suppression of ‘*id quod quaeritur*.’ There is, however, all the difference in the world between taking these data for granted and the *a priori* assertion that we are sure to find skepticism wrong, that the result of our investigation must be the dogmatic thesis that the mind is capable of knowing truth.”¹

Mercier here states that the initial state of mind in setting out to solve the problem of certitude consists in supposing only *two facts*, namely, “the existence of necessary spontaneous assents and the power to examine these by reflection.” But what is this ‘power to examine by reflection’? It is *reason*. Reason is the instrument of reflection. And he intends to use this reason as the instrument of his reflection in examining these necessary spontaneous assents or convictions, although, as he himself states, “we can assert *a priori* neither the essential incapability of the human reason nor its general capability

to know the truth.” But if the *essential* capability of this reason is in doubt, then the whole process of examining these convictions is a doubtful process, and the whole result of this examination (being the result of a doubtful examining faculty) must also remain in doubt: a doubtful reasoning faculty can produce only doubtful conclusions.

Again, Mercier says: “If by dint of reflection we can discover that our mental acts, our assents, are objective, that is, conformable to things as they are in reality, then and then only shall we be able legitimately to infer that our mind is capable of attaining true knowledge.” How are we “to discover that our mental acts are conformable to things as they are in reality”? He gives the answer when he says “by dint of reflection.” And with what are we to make this reflection? With our reason, of course. He, therefore, presupposes that our ‘reason can discover by reflection that our mental acts or assents (spontaneous convictions) actually conform “to things as they are in reality,” and from this “then and then only shall we be able legitimately to *infer* that our mind is capable of attaining true knowledge.” This means that we must *demonstrate* the reliability of our reason by means of a ‘legitimate inference’ from its own acts. The capability of human reason will, therefore, be the conclusion drawn by means of this inference; and this *inference* is made by this very reason whose ‘essential capability’ is in question. The whole process simply *presupposes* the capability of human reason to begin with; and if the ‘essential capability’ of human reason is doubtful, then the whole inference is doubtful, and the ‘essential capability’ of this reason is not, and never can be,

established. The entire procedure is a begging of the question.

Mercier's method can never solve the problem, if the capability of human reason is supposed to be the final outcome of the investigation. This investigation can be valid only if human reason, the instrument of this examination, is known to be valid, and this validity must be established *before* any special investigation is started. And the very fact that Mercier surreptitiously presupposes the capability of human reason in making his investigation and formulating his arguments, although this capability is *still in question*, shows plainly that it cannot really ever be doubted in seriousness without becoming involved in inconsistencies. Mercier, therefore, unwittingly accepts the First Condition, the essential capability of human reason to know truth.

And when he asserts that we must "examine these spontaneous convictions by reflection," he also accepts the dogma of the First Fact, his existence. For how could he 'examine' and 'reflect,' if he were not certain of his own existence *prior* to this examination and reflection? And how can he "by dint of reflection discover that our convictions are conformable to things as they are in reality," if the First Principle, the Principle of Contradiction, did not hold? This 'conformity to things' is, as he states rightly, 'true knowledge.' But how can he know this, unless the Principle of Contradiction be established and accepted beforehand?

Without realizing it, then, Mercier accepts the three dogmas or primary truths. His mitigated or rational dogmatism is an illusion, and he has no right to call the acceptance of the three primary truths an *exaggerated*

dogmatism. We are justified (as we have shown above) in saying of them what he says of immediate propositions: "their very evidence makes them indemonstrable, that is to say, incapable of being referred to propositions which are more evident; and when they are reflected upon by the mind, they necessarily draw its assent, *they force their truth upon the mind.*"

These three dogmas or primary truths are, therefore, *not a priori assertions*, as he contends. They are proved to be 'immediate propositions,' self-evident in their truth, based upon critical reflection; as such they are no longer merely spontaneous convictions, but *reflex and philosophic certainties*.

And thus the basis of human knowledge in its essential foundation is seen to be rational.

Is the problem of knowledge solved by the proof of these primary truths? Not at all. We have merely gained the proper starting point for our investigation of the general problem. We have indeed established the fact that we exist, that it is impossible for something to be and not to be at the same time, and that it would be unreasonable to doubt the capability of but reason to know truth. These are merely preliminary truths, necessary to conduct our investigation; the general problem still remains. We must now examine the data of consciousness, of sense-perception, of intellectual ideas, of first principles, of rational inference, and see whether the spontaneous convictions derived from these sources of knowledge are based on rational grounds and therefore philosophically certain.

SUMMARY OF CHAPTER V

The proper approach to the problem of knowledge must be determined by the purpose of epistemology: namely, to inquire into the rational grounds of our spontaneous convictions, in order to see whether they are justifiable before reason and can thus become philosophic certainties.

1. *Initial State of Mind.* We must accept the data of the problem, in so far as they are subjective facts in our mental life. Since our spontaneous convictions have a strong *prima facie* evidence in their favor, we must accept them as hypothetically true and try to vindicate them. It will be necessary to investigate these convictions as classes. Since we cannot doubt everything, we must begin our inquiry by accepting something as certain. These are the three primary truths: the First Fact, our existence; the First Principle, the Principle of Contradiction; and the First Condition, the essential capability of the mind to know truth.

2. *Proof of Primary Truths.* These primary truths cannot be proved by a positive demonstration, because they are presupposed and involved in every demonstration. But they need no demonstration, because they are so evident that any attempt to doubt or deny them would already mean their affirmation and acceptance. They are, therefore, grounded in reason.

3. *Critical Dogmatism.* These three primary truths are called the 'dogmas of epistemology,' and the system which

accepts these doctrines or principles is called critical dogmatism.

Mercier advocated a mitigated dogmatism. He accepts only two facts: the data of our spontaneous convictions and the power to examine them. Inadvertently, however, he presupposes the validity of these three primary truths. And if the essential capability of reason in its reflection is not admitted, the whole investigation must remain doubtful.

**THE VALIDITY OF HUMAN
KNOWLEDGE**

Section I. EXPERIENCE: Consciousness, Sense-
Perception

Section II. INTELLECTION: Ideas, Judgments,
Reasoning

Chapter 6

THE TRUTH-VALUE OF CONSCIOUSNESS

SECTION I EXPERIENCE: CONSCIOUSNESS, SENSE-PERCEPTION

WE ARE NOW IN A POSITION TO MAKE A CRITICAL INQUIRY INTO THE validity of the various classes of spontaneous convictions of man furnished by the different sources of our knowledge. Skepticism with its universal doubt, as we have seen, is a practical impossibility and a philosophic absurdity; certitude, as a consequence, is and must be attainable. The three primary truths — the First Fact, the First Principle, and the First Condition — have also been established as self-evident and Undeniable certainties; they form the rational starting point from which our investigation can legitimately proceed.

We will now examine the truth-value of the sources of our knowledge. By the *sources of knowledge* we understand the means or *media through which we arrive at truth and certitude*. These are the cognitive operations and faculties of man, as much as it is through them that the knowing subject is brought into contact with objects and through them that these objects become known to the subject. Knowledge, as we have pointed out before, essentially involves three factors — the subject which knows, the object which becomes known, and the cognitive process or act which makes the object known to the subject; the object must act upon the subject, the subject must react to the object by means of a mental assimilation, and is mental assimilation takes place in the process or act of knowledge.

There are *two main sources* of knowledge from which our spontaneous convictions flow: *experience and intellection*. Experience is the source of our knowledge of concrete, individual, contingent facts. It is twofold: *consciousness*, by which we become aware of our intra-mental states and acts; and *sense-perception*, which enables us to apprehend external, material objects. Consciousness is internal experience, while sense-perception is external experience. Intellection comprises three operations — *ideas, judgments, and inferences*; it is the source of our intellectual knowledge of necessary and universal truths. Taken individually and separately, these are the sources of our knowledge which we will have to submit to a critical analysis: consciousness, sense-perception, ideas, judgments, and inferences.

THE PROBLEM OF CONSCIOUSNESS

Since human knowledge begins in the child with external experience or sense-perception, it would seem that sense-perception should be the first source to be examined for its truth-value. We must remember, however, that it is not the validity of the child's knowledge which is at stake, but the validity of *knowledge in general* as we find it in our adult mind. Now, a thing can only become known to us, and knowledge can only become knowledge for us, in so far as we are *conscious of its presence in our mind*. No one denies that our spontaneous convictions are at least subjective facts of our consciousness; they are the acknowledged data of the whole problem. It will be best

then, to begin our inquiry by investigating the truth-value of consciousness itself as a primary source of our knowledge.

A number of important terms have become current in the modern philosophy of knowledge, and great confusion has arisen from the fact that the exact meaning of these terms has not always been recognized and kept distinct in the discussion. They are: *Ego and non-Ego, self and non-self, mental and extra-mental*. Whatever may be their ultimate validity, they have a definite signification, and we should be clear beforehand just what their signification implies. When speaking about the universe in connection with human knowledge, it has become common usage to say that the universe consists of the 'Ego' and the 'non-Ego,' the 'self' and 'non-self,' the 'mental' and 'extra-mental.' This division and designation is taken from the standpoint of man's consciousness. *Ego* is Latin, and it is identical with the English terms 'I,' 'myself,' and 'self'; *non-Ego* is identical in meaning with 'non-self.' By 'Ego' or 'self' we understand man in his whole person, consisting of body and mind together as a unit; and by 'non-Ego' or 'non-self' we understand the whole world which is distinct from man's body and mind and outside his person, as some-king 'other-than-self.' By *mental* we mean anything that belongs and pertains to man's mind, and in this discussion 'mind' is taken in the sense of the 'conscious knowing subject' which is the seat and source of all cognitive and affective states in man; and by *extra-mental* we mean everything found out side, or not pertaining to, the mind. Whether an objective reality corresponds to these terms, is something which will have to be decided later; at present we are concerned only

with the *meaning* which is attached to these words, so that we can discuss the problem of knowledge intelligently. The mutual relationship existing between these sets of terms can be seen from the subjoined diagram:

Parts marked by horizontal lines belong to the Ego. Parts marked by vertical lines belong to the extra-mental.

The most conspicuous thing noticeable in these terms is that 'Ego' and 'extra-mental' are overlapping terms, while 'non Ego' and 'mental' are mutually exclusive. The 'body' of man (if there be a 'body') is considered as an integral part of his person or Ego, together with the mind; but the 'world' (the material world as distinct from man's body, if there be such a 'world') is outside man's person or Ego entirely. At the same time, this 'body' is distinct from man's mind, and it is, therefore, not mental but 'extra-mental.' The body (provided it exists) is thus seen to be a part of the 'Ego' and also 'extra-mental'; as such it is the connecting link between the 'mind' and the material 'world' at large, occupying a middle position between these two extremes.

With these terms and ideas fixed and clear, we are now ready to turn our attention to the problem of consciousness

and its truth-value. The only scientific way to proceed is to examine critically the facts of consciousness and then draw our conclusions concerning the validity of consciousness as a source of true and certain knowledge.

Just what is 'consciousness'? It is the intuitive awareness by which we recognize something as cognitively present in the mind. Now, there is nothing more certain than that we have a 'conscious' mind.

Here are the evident *facts*.

FACTS OF CONSCIOUSNESS

Our mind is aware or conscious of the various acts of *external sense-perception*. I open my eyes and am aware that I see things: my desk, my books, the building outside, an auto turning the corner, the sun shining in the sky. I listen and am aware that I hear sounds: the heavy chugging of the motor of a truck, the conversation of two men passing my window, the scratching of my pen over the paper. I taste the pungent flavor of the piece of candy I am dissolving in my mouth, and I am aware of this sensation. I smell the fragrant odor of the tobacco I have been smoking, and I am aware of this perception. I experience the sensation of touch, and I am aware that I feel things: the hardness and smoothness of the wood of my desk, the pressure exerted by my fingers upon the pen as I write, the coldness of the air as it blows through my open window. All these sensations, as *perceptive acts*, have become *mentally present* to my mind, and I am conscious that they affect me while they are present; if I were not 'conscious' of them, I

could not be aware that I am at this moment seeing, hearing, tasting, smelling, and touching.

Again, I am conscious of the presence in my being of certain *internal sense-states*. I am aware that I feel hunger and thirst, that I have a slight headache, that I am rather fatigued just now, that I experience pleasure in leaning back in my chair and relaxing for a while, that I feel depressed in my nerves. I am also aware that my imagination is evoking images within me of the stroll I intend taking to the library, and of the books I contemplate reading, and of the luncheon I expect to have, and of the persons I plan to meet. And I am aware, too, that my memory is recalling the celebration I attended some time ago and the many friends I met on that occasion after years of separation.

All these sense processes and states are not only present in me, but I experience and feel and am *aware of their presence*: I am conscious of them as actual happenings while they last. I possess a direct and immediate awareness of them as *concrete, individual facts*.

But I am also conscious of a higher order of acts and functions in my being — those of *intellection* and *volition*. As I proceed in my work, I am conscious of forming many ideas, of combining them into manifold judgments and propositions, of linking them together into a variety of inferences and arguments, proofs and refutations; I am thus conscious that I think, judge, reason. Furthermore, I am conscious that I desire to finish a certain portion of my task, and that I decide to continue until I have reached the goal which I have previously set out to attain, and that I

make a distinct effort to overcome the obstacles which make the attainment of this goal a difficult procedure; I am conscious of appetite (conation).

Going a step farther in the introspective analysis of my consciousness, I realize that I possess a reflective power which enables me to obtain *reflex knowledge* of my conscious states and acts. I not only know, but I know that I know; I not only have knowledge, but I have a knowledge of my knowledge; I not only am conscious, but I am conscious of my consciousness. But most important of all: in these various perceptive acts and states of consciousness *I am conscious of my self, my Ego*, as the one in whom they take place and who is the subject affected by their presence. By means of this reflex act of self-consciousness I become aware that I, the thinking and conscious subject, *apprehend myself concretely* in these acts and states; for self-consciousness is the knowledge which the mind has of its acts *as its own*.

When I survey these perceptive acts of my consciousness, I notice that they possess an *objective reference*; that is to say, whenever I 'perceive,' I always perceive an 'object' distinct from the act of perception itself. Thus, when I 'see,' I am not only aware of the act of 'sight' as such, but I am also aware that I see, for instance, 'a green house'; when I press my hand upon my knee, I am not only aware of the act of 'touching' itself, but I am also aware of my 'hand' and my 'knee' as the objects which I feel. And it is my spontaneous conviction that these objects, at least in many instances, are *objectively real*, distinct from their 'mental presence' as 'objects of the mind' in cognition;

in other words, I am convinced that they are *real things* which I perceive.

Is this spontaneous conviction warranted? Have these objects an 'objective existence' aside from their 'mental existence' in the act of perception? Am I justified in passing from the 'mental order' to the 'objective order'? Does my consciousness tell me anything at all about *real, extra-mental things*? If so, what? Is my consciousness a reliable source of true and valid knowledge? These important questions will now have to be answered, and the answer will be the first step in the philosophic justification of human knowledge.

THE TRUTH-VALUE OF CONSCIOUSNESS

Consciousness is a valid source of truth in the domain of knowledge.

Nothing is more intimate and more fundamental to me than my consciousness. All knowledge of whatever kind is rooted ultimately in my consciousness, because I cannot 'know' anything unless I am 'aware' of it. Every single act of sense-perception and intellection becomes an act of 'knowledge' for me only in so far as it conveys some information about an object to me, the subject; I thereby become a knowing subject. But I will be a 'knowing' subject only when I am conscious of the mental presence of the object within my perception and my thinking. If I were unconscious of its presence, I would be totally ignorant of it even as a 'mental object' and I could know absolutely nothing about it. Knowledge must simply be 'conscious'

knowledge, in order to be 'knowledge' at all. Consciousness, therefore, is the indispensable condition of all knowledge, whether sensory or intellectual, so that, so far as I am concerned, knowledge in any form is utterly impossible without it. Consequently, if any knowledge can be true and certain and if any source of knowledge can be reliable at all, it can only be so under the condition that my consciousness is reliable and essentially free from error. If my consciousness is not essentially free from error. I cannot trust any other source of knowledge because no other source is so intimate and evident to me as my consciousness and because every other source presupposes the trustworthiness of consciousness as the basis of its own.

The matter is quite plain and simple. I see, hear, taste, smell, touch; I form ideas, make judgments, produce inferences of deduction and induction. But all these cognitive acts take place in and through my consciousness. Since these cognitive acts are the means whereby I collect and construct my knowledge, and since without them I can have no knowledge at all, it is obvious that the truth and certainty of these sources of knowledge will depend entirely upon the trustworthiness of my consciousness. The reliability of sense and reason, therefore, *presupposes* the reliability of my consciousness; as sources of knowledge they stand and fall with my consciousness. If my consciousness is not essentially free from error, then every part and parcel of knowledge, whether common or scientific or philosophic, will of necessity always remain doubtful in its validity. But that would mean the bankruptcy of all science and philosophy and the suicide of my reason.

There would then be no use in proceeding any further in my inquiry, because my investigation would be doomed beforehand to futility. The inevitable result of such a view would be universal skepticism. But universal skepticism, as was shown above, is a practical impossibility and a philosophic absurdity. If I wish, therefore, to avoid the intellectual death of universal skepticism, I must perforce accept the trustworthiness of my consciousness as capable of giving me true and certain knowledge. This is the only reasonable course for me to pursue, because my consciousness is the last court of appeal before the tribunal of reason, and its verdict is final: if there is any truth at all, the testimony of my consciousness must be true. My consciousness, therefore, is essentially free from error in the acts and facts of which it gives me direct and immediate awareness.

Moreover, if I were to doubt the reliability of my own consciousness as a source of true and certain knowledge, I would, *by my very doubt, assert its reliability*. To have a reasonable doubt, I must have reasons to doubt; otherwise I would act in an irrational fashion. But how can these reasons be valid unless I am certain of their validity? And how can I be certain of their validity, except by an act of consciousness vouching for their presence in my mind? And how can my consciousness vouch for their presence and validity, if it were unreliable? Therefore, even a valid doubt presupposes the reliability of my consciousness, and thereby its reliability is established.

There are a number of things, to which my consciousness testifies as certain facts and truths, which I

cannot possibly doubt, if I am in my right mind. I am certain, for instance, beyond the shadow of a doubt that I exist, that I think, that I perceive, that I reason; I am doing these things at this very moment as I write, so how can I doubt them? It would be sheer nonsense on my part to doubt or deny that I see, touch, hear; taste, smell, imagine, remember, think, judge, reason, considering these acts merely as subjective *facts* present in my mind. They are present as modifications of my being, and no amount of theorizing can argue them out of existence. If they were not present in my mind, and if my consciousness were not reliable in testifying to their existence, how could I know about their presence and think about them? I am *directly and immediately* aware of their existence within my Ego; and this evidence is so clear and irresistible, that I can doubt or deny this testimony of my consciousness only under penalty of renouncing my reason. True, I *cannot demonstrate* the trustworthiness of my consciousness by means of a strict inference, since an inference of this kind would really presuppose the trustworthiness of my consciousness, and that would mean a begging of the question; but such a demonstration is not needed, because all that is required is to show by introspection and analysis that I cannot doubt or deny its reliability without falling into the folly of universal skepticism. And that is clear to me from the above.

My consciousness, therefore, is a valid source of truth in its own domain of knowledge, provided its data are *self-evident*.

TRUTHS REVEALED BY CONSCIOUSNESS

We must distinguish clearly between the data of consciousness and the interpretation of these data. The data are the internal, subjective, intra-mental acts of perception and intellection, emotion and volition, which pass before my consciousness and of whose presence I become aware by the fact that they are there. My consciousness does not pass any judgment upon them but merely notices and registers their presence; and in this 'noticing' and 'registering' it cannot err, because it perceives these internal states by an act of *immediate experience* due to the evidence of its own direct intuition. It is my intellect which passes judgment upon the data of consciousness and interprets them; and here error is possible, since my intellect may mis-interpret the data and draw false conclusions from them. But when my intellect does nothing more than state explicitly what is implicitly contained in the data of consciousness, then my consciousness will also be aware that the interpretation is as true and certain as the data themselves, provided the data are intuitively evident and not vague and indistinct. What truths, then, does my consciousness reveal?

By introspection I discover that every act of knowledge involves three factors — *act of perception, object, and subject*. Directly and primarily, it is the 'act of perception' which is noticed and registered by my consciousness. Since, however, my consciousness is aware of this act of perception in its *concrete* reality, it also notices *in* this act the perceiving subject and the perceived object as concrete

parts of the concrete whole. Thus, when a sensation of 'hunger' arises in my consciousness, I am aware of the 'hunger' which is felt and of 'myself' as the one who 'feels' the 'hunger.' The three factors form a concrete whole, and I am concomitantly aware at the same time of the act of perception, the object, and the subject. I express this in the evident judgment: 'I (subject) feel (perception) hunger (object).' From this triple standpoint my consciousness reveals to me a number of important truths.

From the standpoint of the *act of knowledge*, my consciousness gives indubitable evidence that there is a great *difference* in the character of my acts. 'Hearing' is not the same as 'seeing' or 'tasting,' nor are these perceptions the same as 'touching' or 'smelling': they affect my Ego in different ways. Similarly, the experiences I undergo in the operations of the central sense, imagination, instinct, and memory are unlike each other and differ from the perceptions just mentioned. And all these acts are registered in consciousness as radically different from intellectual ideas, judgments, and inferences. I also perceive within me affective and appetitive states and acts, such as joy, grief, anger, desire, volition; they are non-perceptive states, and the difference between them and the perceptive states is even greater than the differences existing between the perceptive states as such.

Consciousness, of course, does not group these various acts and states into classes; nor does it specify in any way whether they are material or spiritual in nature: it merely 'registers' their existence and their differences in a concrete manner. It is *the intellect* which classifies them by

interpreting the data revealed by consciousness. If an error is made in this interpretation, this is due to a faulty analysis on the part of the intellect. Consciousness itself can never be mistaken in its clear testimony of the presence of an act or state within the mind.

FROM THE STANDPOINT OF THE *OBJECT OF KNOWLEDGE* MY consciousness is concretely aware of the object of perception at the same time that it is aware of the *act* of perception. I cannot 'perceive' without perceiving 'something,' an object; and I thus become aware of colors, sounds, flavors, odors, tactile objects of sensation (heat and cold, hardness and softness, muscular and motor feelings), ideas, judgments, and inferences, as the objects of the various operations of my sense and intellect. I can no more deny their presence and existence within my consciousness than I can deny the presence and existence of the perceptive acts themselves, because *act and object form one concrete whole*. At the same time I am aware of their concrete difference: sounds are not colors; muscular feelings are not flavors; odors are not heat or cold; and all these sense-objects are not ideas or judgments or inferences.

Then again, I am intuitively conscious of *extendedness* in or the other of my perceptions. Color- perception always reveals *colored surfaces*, not merely color alone for itself. There is a side-by-sideness of spatial parts in all color-objects, and extendedness in at least two dimensions — length and width. I never see 'green' alone; but I see a

'green lawn,' a 'green sea,' 'green leaves,' a 'green house.' I never see 'blue' alone; but I see a 'blue sky,' 'blue violets.' I never see 'red' alone; but I see 'red sealing-wax,' 'red roses,' 'red sunsets.' And so with the other colors: they are always extended and surfaced. Moreover, these extended surfaces are consciously perceived as having concrete *shapes*, and these shapes are recorded as having a concrete *difference* among themselves. I am intuitively aware of squares, triangles, disks, ellipses, and every kind of irregular figure in these colored surfaces. For instance, what I call an 'orange' is not merely 'yellow,' but a 'round' yellow object; the 'house' I see is a 'square' brown object; the 'moon' I perceive is a 'crescent-shaped' silvery object; the 'rose' I am looking at is an 'irregularly shaped' red object. These various configurations of shape are given directly with the color-object as an 'extended colored surface,' and my consciousness makes me immediately aware of them in the act of color-perception. *In some form*, therefore, *extension must exist*, otherwise it could not be a datum of my consciousness.

Similar to sight, but in a somewhat different manner, *touch reveals extension*. The sensation of side-by-sideness of spatial parts is even more immediately and intimately a datum of my consciousness in touch than it is in the sight of colored surfaces, because there is a *direct contact* in touch which is missing in the act of sight. When I pass my hand over a book, I *feel* the spatial extendedness of the book, and this contact-experience gives to the sensation a value which cannot be denied. Sight reveals a two-dimensional extension, but touch reveals dimension in three directions.

When I handle a book, a pen, a bottle, an apple, or when I grasp my left wrist with my right hand, or when I feel my head with both hands, I am concretely conscious of *solidity, voluminousness, triple dimension*. Besides this, my consciousness reveals the difference of a total 'otherness,' when I touch my arm or head or thigh, and when I touch a book or a table or a fruit. The former are perceived to *be a part of my being*, while the latter are foreign to myself and 'outside' my being. This will become clearer, when we analyze the 'subject' of the act of knowledge.

From the standpoint of the *subject of knowledge*, my consciousness reveals a number of most interesting and vital truths. Primarily, I am aware of the acts of sense-perception and intellection which are present within me as concrete states of knowledge; but just as these acts manifest the object perceived, so they also reveal the *perceiving subject*, and this subject is my self, my *Ego*. Nothing is clearer to my consciousness than the fact that I myself am the active and passive subject of all internal states and modifications which I recognize as coming and going within me. All perceptive acts and affective states I concretely observe to be my own; they belong to *me* and modify *me*. Analyzing the data of my consciousness, I perceive with intuitive evidence that it is I who hear, see, touch, taste, and smell; it is I who imagine and remember; it is I who think, judge, and reason; it is I who am hungry and thirsty, sad and glad, peaceful and angry, healthy and sick, in pleasure and in pain; it is I who decide and will, strive and reject. It is my *selfsame Ego* which is active throughout, whether in the domain of sense or in the domain of intellect,

and my Ego is one, single individual; there is no duality or multiplicity here, notwithstanding the radical difference between the acts and states themselves. Even my consciousness is only a modification of my self or Ego, because I am conscious of *myself as conscious* in the same way that I am conscious of myself as seeing, hearing, thinking, and willing; I express both facts in an identical manner, namely, '*I hear a sound*' and '*I am conscious myself.*'

The Ego is not consciousness; it is the *possessor* of consciousness. The Ego is not experience; it is the *experient*. And so, too, the Ego is not memory; it is the bearer of memory. The act of remembering is a present act, but it always has a reference to past persons or events. I perceive with evidence that I, the Ego, who am conscious at this very moment, am the *self identical Ego* who have had the 'past' experiences recorded my memory. I am writing at this instant; but I am also conscious through my memory that I was writing ten minutes ago, that I took a walk half an hour ago, that I consulted a physician this morning. Notwithstanding the fact that I was in a state of complete unconsciousness during my sleep last night, I am aware that 'I' am the self-identical 'Ego' who existed, worked, ate, wrote, perceived, and reasoned yesterday, a week before, a month ago, and through all the years down to my youth and childhood. These events belonged to me before; and my Ego preserved its self-identity, while they came and passed on. How could I remember them as mine, as having happened to 'me,' if my Ego were not a permanently existing reality in whom they occurred? My Ego is clearly

perceived to be the *abiding subject* of these transitory states. It is the duty of psychology to pass judgment on the nature of the Ego, but the data of my conscious states show plainly that my Ego is distinct from the conscious states themselves; the latter are only modifications of the permanent Ego, existing *in and by and through* my Ego as their agent-patient subject. So much is evident to me from an analysis of the data of memory.

Of what does my Ego consist, so far as I am informed by my consciousness? Since the Ego is the 'thinking subject,' whatever is 'mental' belongs to it; the mind, therefore, is an integral part of the Ego. But some of my perceptions also show that my Ego is an *extended reality*. When I grasp a book or a pen, I am aware that these objects are extended and that they are 'other-than-self'; however, when I grasp my arm or my head or my ankle, I am aware that they are extended and that they differ among themselves, but also that they are 'identical-with-self.' In other words, they are perceived to be *integral parts of my Ego*, they belong to my being and my person; they are 'my head,' 'my eyes,' 'my ears,' 'my hands,' 'my chest,' 'my arms,' 'my legs,' 'my toes.' Hence, if I stub the toes against a stone, I say: 'My foot hurts,' and 'I feel a pain in my foot.' Since these objects are clearly perceived by touch and sight to be extended, and since my consciousness testifies that they belong to me as integral parts of my Ego, it is obvious that my *Ego is extended with and through them*. These parts, however, taken together, form what we call the 'body,' and this body is clearly perceived to be distinct from the 'thinking subject' or mind; the body is 'extra-mental.' My Ego, therefore,

according to the indisputable evidence of my consciousness, consists of something 'mental' and 'extra-mental,' of *mind and body*. It is, then, untrue to say that the Ego consists of purely mental states; it also consists of an extra—mental body which has various extended parts side by side; and both mind and body form a unit, the one and *undivided whole* which is my Ego.

Such are the facts of consciousness regarding the *act, object, and subject* of knowledge. And it is from such evident, undeniable facts that my intellect forms such ideas as 'being, existence, sense-perception, intellection, appetition, extension and space, mind and body, mental and extra-mental, Ego and non-Ego.' They are not mere fancies and figments, but *valid ideas*, possessing objective reality, derived by the intellect from the critically observed and analyzed data of my consciousness; and, as we see, they are not the results of a blind instinct, but the conscious products of an intellectual insight based on the intuitive evidence of immediate experience which cannot be doubted or denied without falling into complete skepticism. Any 'immediate judgments' then, which my intellect forms as interpretations of these facts by means of such ideas, must be as *true, valid, and certain* as these facts themselves, because my consciousness testifies that in such instances my intellect is merely stating explicitly that which is contained implicitly in the data as mentally present. Such immediate judgments are: 'I exist; I am a being; I experience various acts of sense perception, intellection, and appetition, and there is an objective difference between them; extension is a reality; I possess an extended body; I

have a mind; my body is an extra-mental reality as certainly existing as my mind; mind and body are integral parts of my Ego; I, the Ego, am the possessor of this mind-body combination; I have perceptions of objects which I consciously apprehend as being outside my Ego and as belonging, therefore, to the 'non-Ego.' These immediate judgments are now no longer simply spontaneous convictions but scientific, *reflex, philosophic truths and certainties*, the result of a critical analysis of my conscious mind in its revealed data. It will be obvious that these ideas and truths are basic to the problem of knowledge and must be considered as partly solving the problem. The validity of the 'body' and of the external 'world' as 'objective realities' will be treated later.

Consciousness, then, is a valid source of true and certain knowledge concerning those acts and facts of which it has immediate cognition. This validity is based on the indubitable evidence of *primary experience*. To doubt the essential freedom from error on the part of consciousness is to destroy the validity of any and all other knowledge, because such knowledge has its ultimate foundation in the intuitive character of the knowledge of consciousness.

SUMMARY OF CHAPTER VI

1. The sources of knowledge are the media through which we arrive at truth, and they are twofold: experience and intellection. *Consciousness*, a form of experience, is the intuitive awareness by which we recognize something as 'mentally present.' 'Ego' and 'non-Ego,' 'self' and 'non-self,' 'mental' and 'extra—mental,' are cognate ideas whose meaning should be clearly grasped.

2. We possess a *conscious mind*. We are aware of sense-perception, intellection, and appetite. Consciousness reaches its highest expression in the knowledge of *Ego or self*; the Ego observes itself concretely as the subject and bearer of the internal acts and states of consciousness. All perceptive acts have an 'objective reference.'

3. Consciousness is *essentially free from error* in the knowledge it conveys, when the data are perceived with intuitive evidence. Otherwise no other knowledge would be valid, and certitude would be impossible, because all other forms of knowledge presuppose the validity of consciousness. To doubt the validity of consciousness is tantamount to asserting its validity, since the reasonableness of this doubt could not be established except on the supposition that consciousness is a valid source of knowledge. Some facts attested by consciousness are so obviously true, that we cannot doubt them except under penalty of renouncing our reason. If consciousness is not essentially free from error, universal skepticism must follow.

4. The act of knowledge reveals the various kinds of internal states and their differences in a concrete manner. The *object* of knowledge reveals the objects of various perceptive and non-perceptive acts and their concrete differences. In particular, sight reveals extension in two dimensions, while touch reveals it in three dimensions. Touch also shows that part of my own being is extended. The *subject* of knowledge reveals the fact that my self or Ego is the active and passive agent of all internal states, that my self or Ego possesses a mind and body as a unit.

Chapter 7

DEVELOPMENT TO IDEALISM

THE PROBLEM OF THE VALIDITY OF SENSE-PERCEPTION IS THE crucial problem in modern epistemology. It is the dividing point of the various theories of human knowledge. Depending on their interpretation of the cognitional value of sense-perception, philosophers and scientists have devised the most divergent systems in order to explain the facts so obvious to all. The fundamental facts are admitted. All agree that sensations are real in so far as they are subjective, mental states of the knowing subject: we see colors, hear sounds, taste flavors, smell odors, and feel pressure and resistance, heat and cold, pleasure and pain, muscular and organic conditions. But as to whether the perceived *objects* are *purely intra-mental* and *intra-subjective*, or whether they are *extra-mental* and *extra-subjective*, the interpretations are as far apart as the poles. People in general have the spontaneous conviction that the world which they perceive is physically real, with a reality independent of the mind and its perception.

The problem thus arises: Is this spontaneous conviction true and valid? And this proposes further questions: Do our sense-perceptions reveal to the mind an extra-mental and

extra-subjective reality? Can the mind transcend itself and contact an external world? Can the physical world (if there be a physical world) become intra-mental through sense-perception, so that the mind can know its existence and nature? How can an extended world make an impression on an unextended mind, and how can an unextended mind conform itself to an extended world?

The problem is by no means so simple as it seems. There are grave difficulties in either view. In order to appreciate the importance of the problem, it will be necessary to review briefly its *origin* and *development* from Descartes up to the present day.

DESCARTES' ULTRA-SPIRITUALISM

Descartes' views on the nature of mind and matter and on the validity of human knowledge have been largely responsible the widespread confusion in subsequent philosophy and for the rise of numerous theories of knowledge. By means of his methodic doubt he called all accepted truths into question, discarded the validity of all human knowledge, and attempted place philosophy upon a new foundation. This attempt was futile, but the seed of doubt was sown and produced abundant fruit. It was particularly in the domain of *sense-perception* that the destructive influence of his criticism became apparent. Here is his own line of reasoning concerning the truth-value of sense-perception.

"Merely because I know with certitude that I exist, and because, in the meantime, I do not observe that aught

necessarily belongs to my nature or essence beyond my being a thinking being, I rightly conclude that my essence consists only in my being a thinking thing [or a substance whose whole essence or nature is merely thinking]. And although I may, or rather, as I shall shortly say, although I certainly do possess a body with which I am very closely conjoined; nevertheless, because, on the one hand, I have a clear and distinct idea of myself, in as far as I am only a thinking and unextended thing, and as, on the other hand, I possess a distinct idea of body, in as far as it is only an extended and unthinking thing, it is certain that I [that is, my mind, by which I am what I am], is entirely and truly distinct from my body, and may exist without it.”¹ “Extension in length, breadth, and depth, constitutes the nature of corporeal substance; and thought the nature of thinking substance. For every other thing that can be attributed to body presupposes extension and is only some mode of an extended thing; as all the properties we discover in the mind are only diverse modes of thinking. Thus, for example, we cannot conceive figure unless in something extended, nor motion unless in extended space, nor imagination, sensation, or will, unless in a thinking thing.”²

LET US PAUSE AND DIGEST THESE PRINCIPLES. THE ESSENCE OF the mind is ‘thought,’ and thought is ‘thinking.’ Descartes included in this ‘thinking’ all intellection, willing, and sense-perception; in short, the essence of ‘the mind, by which I am what I am,’ consists in the *conscious states*. The Ego,

therefore, consists solely in consciousness; the body is outside the Ego. There is, of course, a human body, to which the mind is 'closely conjoined'; but the two do *not* form an *organism* in any way, so that the mind would be a vitalizing principle or agency or soul, making the body-soul compound a living subject capable of sense-perception. All sense-perception takes place in the mind only. The mind is united to the body only in the brain (in the pineal gland, according to Descartes), and all nerve-tremors concentrate in the brain; since, however, the essence of matter is 'extension' and the essence of mind is 'thought,' there can be *no cognitional communication between mind and body*, because the disparity between them is too great. What really happens is that certain 'corporeal movements' of the body reach the brain, and at the *occasion of their presence the mind* produces the ideas or representations of external and extended things entirely in itself and by itself. Ideas are thus potentially *innate*.

That Descartes really meant this is clear beyond a doubt. "I suppose that the body is merely a statue or earthen machine made by God on purpose to resemble us as much as possible. . . I want you to consider that all the functions which I have attributed to this machine [the human body], such as the digestion of meat, the pulsation of the heart and of the arteries, the nourishment and growth of the limbs, breathing, waking and sleep, seeing, hearing, smell, taste, feeling hot, and any other properties of the external senses; the impression of their ideas upon the organ of the common sense and of the imagination, and the retention or imprinting of these ideas upon the memory; the internal

movements of the appetites and passions; and lastly, the external movements of all the members which follow so opportunely the many operations of the things that are presented to the senses as well as the passions and impressions that are to be found in the memory, that they imitate so closely those of a real man — I want you, I say, to consider that *these functions quite naturally follow in this machine from the mere arrangement of the organs, neither more nor less than the movements of a clock or other automaton, from its weights and works*, so that so far as they are concerned we need *not think of any vegetative or sensitive soul in it, or of any other principle of life or motion* than the blood and the spirits continually stirred up by the fire constantly burning in the heart, a fire which does not differ by nature from any other fires to be found in other inanimate bodies.”³

It is in this manner that Descartes reduced the mind to thought and its activities to states of consciousness, while he reduced all matter (including the human body) to extension and its activities to mechanical motion. This absolute opposition and disparity between mind and matter gives to his philosophy a double characteristic: an *ultra-spiritualistic* interpretation of the mind, and an *ultra-mechanistic* interpretation of the body and of the extra-mental and external world.

THE FUNDAMENTAL MISTAKE OF DESCARTES CONSISTED IN HIS arbitrary assumption that the essence of the mind consists in ‘thinking’ and in ‘thinking’ only. He had no right to

restrict the essence of the mind to 'thought.' If the activities of man demand that the Ego possess a living soul united to the body with the triple functions of *vegetation, sentiency, and 'thinking,'* so that body and soul form a joint living organism together, and if sense-perception cannot be explained except by means of an organic union between mind and body, then Descartes committed an unpardonable error in arbitrarily limiting the essence of the mind to 'thought' alone. When he stated 'I think, therefore I exist,' he expressed a fact which was indubitably true: 'thinking' is a primary experience of the Ego, an evident datum of intuition. But he overlooked the fact that *'thinking' was not the only primary experience revealed by consciousness.* I am equally conscious that I walk and eat and drink, taste and smell and hear, see and touch; I am conscious that my body has a part in these activities, and that these activities are as real and actual as 'thinking'; and I am also conscious that these activities reveal objects-other-than-self. These are vital activities which are also bodily and extended. What right, then, had Descartes to assume that the body is a mere machine and exclude it from the Ego and its vital functions? This is an arbitrary and one-sided restriction which does violence to the facts recorded by consciousness.

Descartes, of course, defended the dualism of mind and matter, of the world of the Ego and of the world of the non-Ego; but this was an *excessive dualism*, making any interaction between them unintelligible. The theory that soul and body form a unitary organism is the *aristotelian-scholastic* view. This theory had been the traditional doctrine for centuries. In discarding it for his own ultra-

dualistic theory, Descartes rendered a doubtful service to philosophy, because the problem of finding an *epistemological bridge* between mind and body now became the crucial problem of modern philosophy. Chaos followed the Cartesian riddle. Since his endeavor to found a philosophy ‘without presuppositions,’ it became a philosophic dogma that the only certain thing man can know is his own mind and its conscious states.

OCCASIONALISM, ONTOLOGISM

Arnold Geulincx (1625—1669) and *Nicholas Malebranche* (1638—1715) developed the teachings of Descartes. Since there can be no causal interaction between mind and body, the evident co-ordination existing between them can only be the result of God’s causality. On the occasion of bodily stimuli, God produces corresponding ideas in the mind; and on the occasion of ideas and volitions in the mind, God produces corresponding motions in the body: creatures are mere instruments of God’s action. This is occasionalism. Malebranche went a step farther. Instead of Descartes’ theory that man acquires his knowledge from innate ideas, he maintained the view that man’s mind envisions all things by means of a direct intuition of God’s ideas. This theognostic theory is called *ontologism*.

SPINOZISM, MONADISM

Baruch Spinoza (1632—1677) chose a different solution for the problem cast up by Descartes in his arbitrary definition

of mind and matter. The latter's definition set up an irreconcilable opposition between the world and the mind. Spinoza attempted to bring them into a higher unity, thereby dissolving all differences between them. He defined 'substance' as that which exists in itself and is conceived by itself, so that it does not need the concept of another in order to be understood. Now, there can be only *one such substance*, as expressed this definition, and that is the infinite substance, God. This infinite substance has as its attributes 'extension' and 'thought.' Considered under the determination of 'extension,' God is nature or matter; considered under the determination of 'thought,' God is the human mind. And thus Descartes' antithesis between mind and matter is resolved in the higher unity of the infinite substance: God and all beings are one in substance. This is *pantheistic monism*. This absolute, metaphysical monism is, of course, the very opposite of Descartes' dualism. *Gottfried W. Leibnitz* (1646—1716) sought to equalize the difference between mind and matter in the opposite direction. The ultimate beings are individual *monads*. Monads are absolutely indivisible; no two are alike; and all possess the 'power of representation.' Each monad in its representation mirrors within itself whatever takes place in all other monads throughout the universe; some do it consciously, like the mind-monads, others unconsciously, like ordinary body-monads. Each monad is thus a little universe, endowed with the attributes of 'extensions and 'thought.' All knowledge is *innate*: the monads are 'windowless.' The knowledge of each monad corresponds with the facts of external reality by means of a pre-established harmony

which God placed in them. Mind and body, therefore, do not interact, but they are like two clocks running in perfect coordination. By thus postulating that all bodies have minds and all minds have bodies (pan-psychism), Leibnitz was convinced that he had overcome Descartes' ultra-dualism.⁴

EMPIRICISM, PSYCHOLOGICAL IDEALISM

John Locke (1632—1704) strenuously opposed Descartes' doctrine of innate ideas. All knowledge has its origin in *experience*, in sense-perception. The elements of knowledge are the *ideas*, and Locke explains the idea in the following manner: "It being that term which, I think, serves best to stand for whatever is the object of the understanding when a man thinks, I have used it to express whatever is meant by *phantasm*, *notion*, *species*, or whatever it is which the mind can be employed about in thinking."⁵ Descartes placed all sense-perception in the spiritual mind, thus identifying sense-perception with spiritual activity; Locke here does the reverse, by reducing ideas, at least in part, down to the level of sense-perception (phantasm, species). By thus arbitrarily blurring the nature of the 'idea' so as to include sense-perception, he laid the foundation for *sensism*, where all 'thinking' is nothing but a form of 'sensation.' Another important feature of this definition of 'idea' is, that the 'idea' is the *object* of our understanding, instead of the reality of things being the object of our knowledge.

Ideas, according to Locke, are derived from two sources sense-perception and reflection; and all knowledge is

restricted to ideas. "Since the mind, in all its thoughts and reasonings, hath no other immediate object but its own ideas, which it alone does or can contemplate, it is evident that our knowledge is only conversant about them. *Knowledge, then, seems to me to be nothing but the perception of the connection of and agreement, or disagreement and repugnancy of any of our ideas.* In this alone it consists."⁶ This means, of course, that we do not really know objects or things-in-themselves, but ideas or conscious states of the mind; and this is the standpoint of Descartes and idealism. Locke, however, did not deny the existence of material substances, such as bodies, nor of spiritual substances, such as the soul and God; but 'substance' is unknowable to us, whether material or immaterial. "Our idea of substance is equally obscure, or none at all, in both: it is but a supposed I-know-not-what, to support those ideas we call accidents. . . . By the complex idea of extended, figured, colored, and all other *sensible qualities, which is all that we know of it*, we are as far from the idea of the substance of the body, as if we knew nothing at all."⁷ While Locke, therefore, admits the existence of material and spiritual 'substances,' he asserts that they are unknowable; 'accidents' or 'phenomena' alone are knowable: he is in last instance an *empirical phenomenalist*.

George Berkeley (1685—1753) took issue with Locke. He pointed out the inconsistency of Locke in maintaining that knowledge is limited to ideas only and then asserting that have a sense-knowledge of the qualities of extra-mental objects. Berkeley accepted the initial standpoint of Descartes and Locke that 'the mind can know nothing but

its own ideas or conscious states'; but from this he drew the conclusion that *all things are ideas and a physical world does not exist*. Ideas are the sole 'objects of cognition' for the mind; things, therefore, have 'being' only in so far as they are 'perceived' (*esse est percipi*). Physical things, being outside the mind, cannot be perceived at all; consequently, they are nonexistent.

We observe Berkeley's trend of thought in the following quotations. "It is evident to any one who takes a survey of the *objects of human knowledge*, that they are either ideas actually imprinted on the senses; or else such as are perceived by attending to the passions and operations of the mind; or lastly, *ideas* formed by help of memory and imagination.... That neither our thoughts, nor passions, nor ideas formed by the imagination, exist without the mind is what everybody will allow. And to me it seems no less evident that the various sensations or ideas imprinted on the Sense, however blended or combined together (that is, whatever objects they compose), cannot exist otherwise than in a mind perceiving them. I think an intuitive knowledge may be obtained of this, by any one that shall attend to what is meant by the term exist when applied to sensible things. The table I write on I say exists; that is, I see and feel it: and if I were out of my study I should say it existed; meaning thereby that if I was in my study I might perceive it, or that some other spirit actually does perceive it. There was an odor, that is, it was smelt; there was a sound, that is, it was heard; a color or figure, and it was perceived by sight or touch. This is all that I can understand by these and the like expressions. For as to what is said of

the absolute existence of unthinking things, without any relation to their being perceived, that is to me perfectly unintelligible. Their *esse* [being] is *percipi* [being perceived]; nor is it possible they should have any existence out of the minds or thinking things which perceive them.

“It is indeed an opinion strangely prevailing amongst men, that houses, mountains, rivers, and in a word all sensible objects, have an existence, natural or real, distinct from their being perceived by the understanding. But, with how great an assurance and acquiescence soever this Principle may be entertained in the world, yet whoever shall find in his heart to call it in question may, if I mistake not, perceive it to involve a manifest contradiction. For, what are the forementioned objects but the things we perceive by sense? and what do we perceive besides our own ideas or sensations? and is it not plainly repugnant that any of these, or any combination of them, should exist unperceived?

“From what has been said it is evident there is not any other Substance than Spirit, or that which perceives. But, for the fuller proof of this point, let it be considered the sensible qualities are color, figure, motion, smell, taste, and such like, that is, the ideas perceived by sense. Now, for an idea to exist in an unperceiving thing is a manifest contradiction; for to have an idea is all one has to perceive: that therefore wherein color, figure, and the like qualities exist must perceive them. Hence it is clear there can be no unthinking substance or *substratum* of these ideas.”⁸

According to Berkeley, then, physical, external objects have no existence of their own: their *esse* is *percipi*. Locke

considered the 'secondary' qualities (color, taste, sound, heat, etc.) to be subjective, but the 'primary' qualities (extension, figure, motion, etc.) were real and objective. Berkeley reduces primary and secondary qualities and *all material things* to 'ideas' whose sole existence consists in 'being perceived': there are no material objects as such. This is idealistic immaterialism. The only realities which exist are God and human minds. How then account for our ideas of extra-mental and external objects, like the human body and the physical world? They are not the product of the human mind, they are objectively produced by God in the mind, *as if* there were a real world outside us. Berkeley is a psychological and acosmistic *idealist*.

PAN - PHENOMENALISM

David Hume (1711—1776) went a step farther. He denied the existence of *all* substances. "I would fain ask those philosophers, who found so much of their reasonings on the distinction of substance and accident, and imagine we have clear ideas of each, whether the idea of *substance* be derived from the impressions of sensations or reflection? If it be conveyed to us by our senses, I ask, which of them; and after what manner? If it be perceived by the eyes, it must be a color; if by the ears, a sound; if by the palate, a taste; and so of the other senses. But I believe none will assert, that substance is either a color, sound, or taste. The idea of substance must therefore be derived from an impression of reflection, if it really exist. But the impressions of reflection resolve themselves into our

passions and emotions; none of which can possibly represent a substance. We have therefore no idea of substance, distinct from that of a collection of particular qualities, nor have we any other meaning when we talk or reason concerning it.”⁹ And thus all substances — physical bodies, soul, God — are argued out of existence. The only things which we know to exist are *phenomena*, and the mind consists of nothing but a heap or collection of different perceptions united by certain relations. This is *pan-phenomenalism* and extreme *subjectivism*. Hume ended as a skeptic.

TRANSCENDENTAL IDEALISM

Emmanuel Kant (1724—1804), alarmed at the trend of thought manifested by the English philosophers, especially Hume, felt the urge to re-vindicate human knowledge. Like them, however, he took as his starting point the principle of Descartes that the mind of man can know only its own internal states and cannot go outside and beyond the limits of consciousness. He considered it to be the essential error of all previous philosophic systems that they endeavored to make the mind conform to the objects; he would reverse the principle and make the *objects conform to the mind*. “Hitherto it has been supposed that all our knowledge must conform to the objects; but, under that supposition, all attempts to establish anything about them *a priori*, by means of concepts, and thus to enlarge our knowledge, have come to nothing. The experiment therefore ought to be made, whether we should not succeed better with the

problems of metaphysic, by assuming that the objects must conform to our mode of cognition, for this would better agree with the demanded possibility of an *a priori* knowledge of them, which is to settle something about objects, before they are given us.”¹⁰

Before entering upon Kant’s views on the nature of sense-perception, it will be necessary to understand what he means by *a priori* and *a posteriori* knowledge; this distinction is the basis of his theory.

“It is therefore a question which deserves at least closer investigation, and cannot be disposed of at first sight, whether there exists a *knowledge independent of experience*, and even all impressions of the senses? Such knowledge is called *a priori*, and distinguished from empirical knowledge, which has its sources *a posteriori*, that is, in experience. . . .”¹¹

There is, then, according to Kant, a double knowledge (and consequently also a double source of knowledge) in the man mind: knowledge *a priori*, independent of all experience; and knowledge *a posteriori*, derived through experience. How can we tell which knowledge is the one and which is the other? Experience can reveal nothing to us except what is *individual and contingent*; it never reveals to us anything that is strictly universal and necessary. “Experience teaches us, no doubt, that something is so or so, but not that it cannot be different. . . . Experience never imparts to its judgments true or strict, but only assumed or relative, universality (by means of induction), so that we ought always to say, so far as we have observed hitherto, there is no exception to this or that rule. If, therefore, a

judgment is thought with strict universality, so that no exception is admitted as possible, it is not derived from experience, but valid absolutely a priori. Necessity, therefore, and strict universality are safe criteria of knowledge *a priori*, and are inseparable one from the other."¹² Whenever, therefore, knowledge is *strictly necessary and universal*, it is a priori and cannot have been acquired through experience. Such *a priori* knowledge must proceed directly *from the mind itself*.

There are various elements which enter into the making of our empirical knowledge or sense-perception, and Kant is explicit in explaining the process through which our knowledge must be acquired in experience. Here is the process in his own words:

"The effect produced by an object upon the faculty of representation (*Vorstellungsfähigkeit*), so far as we are affected by it, is called sensation (*Empfindung*). An intuition (*Anschauung*) of an object, by means of sensation, is called empirical. The undefined object of such an empirical intuition is called phenomenon (*Erscheinung*)."

"In a phenomenon I call that which corresponds to the sensation its matter; but that which causes the manifold matter of the phenomenon to be perceived as arranged in a certain order, I call its form."

"Now it is clear that it cannot be sensation again through which sensations are arranged and placed in certain forms. The matter only for all phenomena is given us a posteriori; but their form must be ready for

them in the mind (*Gemüth*) *a priori*, and must therefore be capable of being considered as separate from all sensations. . . . In the course of this investigation it will appear that there are, as principles of *a priori* knowledge, two pure forms of sensuous intuition (*Anschauung*), namely, *Space and Time*."

Kant

Bearing in mind Kant's axiom that nothing necessary and universal can be derived from experience, but must proceed exclusively and *a priori* from the mind itself, Kant finds that sense-perception contains a double element: the 'manifold' of sense impressions, which is derived from experience, and 'space' and 'time,' which are pure forms of the mind. External to the mind there exists a world of things-in-themselves (*Dinge-an-sich*) or noumena; they are real, physical beings. These make impressions on the sense-faculty, and the faculty responds with an 'intuition' or perception. These impressions are unarranged, chaotic. This chaotic 'manifold' must be arranged in a certain order, and this is done by means of the two sense-forms 'space' and 'time.' Space and time are *in no way attributes of the things-in-themselves*,¹³ but merely "cause the manifold matter of the phenomenon to be perceived as arranged in a certain order," i.e., as arranged in the order of 'space' or in the order of 'time.' Since all intuitions or perceptions appear as arranged in a spatial and temporal order, 'space' and 'time' are universal and necessary conditions of sense-perception and as such must exist *a priori* in the mind. They

are like mental molds into which the unarranged raw materials of sense are poured, so that, after the molding process of cognition is completed, all phenomena appear arranged and molded in 'space' and 'time.' The objects themselves are, so far as we know, spaceless and timeless.

Do we really perceive external objects, so that the objects of sense actually exist, as we perceive them, outside our person? We do not. The real objects of the physical world can never be perceived; we know absolutely nothing about the noumena or things-in-themselves: "All our intuition is nothing but the representation of phenomena. . . . Nothing which is seen in space is a thing-in-itself, nor space a form of things supposed to belong to them by themselves, but objects by themselves are not known by us at all, and that what we call external objects are nothing but representations of our senses [*phenomena*]." ¹⁴ All we can know, then, are the *phenomena* or appearances, and these are always subjective in character, without any resemblance to the things-in-themselves. Even man's perception of his own body is thus seen to be only 'phenomenal'; whether any extra-mental reality corresponds to what he perceives to be his 'body,' man can never know. Kant admits the existence of things-in-themselves as the *exciting cause* of sense-perception on the grounds of inference; but they remain an unknown and unknowable X. Kant is thus a *hypothetical realist and dualist*; since, however, all our knowledge in sense-perception is limited to intra-subjective phenomena, he is a *transcendental idealist*. He failed to overcome the Cartesian antithesis between mind and matter; the mind remains

imprisoned in its conscious states and can know nothing of the external world and non-Ego objects.

ABSOLUTISM

Kant's philosophy left the antithesis between mind and matter, noumenon and phenomenon, the thing-in-itself and the Ego, unsolved; the unity between these opposing elements, so evident in our knowledge, was still unexplained. His followers in idealism attempted to develop his ideas to their logical conclusions.

Johann Fichte (1762—1814) took up Kant's principle that the 'things must conform to the mind' and dissolved the antithesis between the Ego and the 'thing-in-itself' by *identifying all reality with the Ego*. It was his contention that thought cannot be deduced from being, but being must be deduced from thought; *thought, therefore, is the ultimate and only reality*, and the Laws of thought are the laws of being. And since all thought is contained in consciousness, there is no other reality but the Ego; hence, all reality is unified in the Ego. The Ego, of course, does not mean merely human consciousness, but the universal consciousness of the Absolute or God. Such is Fichte's system of *Pan-Egoism*.

Friedrich Schelling (1775—1854) propounded a number of theories at variance with each other. His third system is most characteristic of his thought. Like Fichte, he sought a common formula or principle in which mind and matter, spirit and nature, could be harmonized. He also identified the real and the ideal in the Absolute; but while Fichte

derived them from the 'self-activity' (*Tathandlungen*, deed acts) of the Absolute (Universal Ego), Schelling derived the ideal and the real (subject and object, spirit and nature, mind and thing-in-itself) from the *indeterminateness* of the Absolute. Because the Absolute is 'indeterminate' in its being, it gives rise to the ideal and the real in its development, so that they are but two phases of the ultimate reality which is the Absolute.

Georg Hegel (1770—1831) also identified all things in the Absolute. But with him the Absolute is pure Thought or Idea, dynamic with immanent activity, not static like Schelling's 'indeterminateness.' Since the Absolute is pure Idea, it evolves by means of a purely *logical and rational process of thought* into the ideal and real, into subject and object, into spirit and nature, into mind and matter. The Absolute is continually in a dialectic evolution, so that all being is thought realized. His system is idealism driven to its highest peak.

It is difficult to compress the vastness of Hegel's system into a brief survey. According to him, all reality is idea, and the laws which govern the development of idea are the identical laws which govern the development of reality. Nature and spirit do not proceed from the Absolute, as Schelling stated, but the Absolute gradually becomes nature and spirit in a process of self-actualization. It is the law of development for thought and being (for both are the same) to realize itself by passing from a state of *in-itself* (*an-sich*) through the state of *out-of-self* (*für-sich*, otherness) into the state of *for-itself* (*an-und-für-sich*). The dialectic or logical movement of evolution thus comprises

three stages: the position or *thesis*, the contraposition or *antithesis*, and the identity of position and contraposition or synthesis; or, to express it in a different way — affirmation, negation, and the negation of negation.

This self-evolution of the Absolute begins with Being. Being is abstract, indeterminate, empty of all content, and as such it is indistinguishable from Nothing. Here is Hegel's view: "The distinction between Being and Nought is, in the first place, only implicit, and not yet actually made: they only *ought* to be distinguished. A distinction, of course, implies two things, and that one of them possesses an attribute which is not found in the other. Being, however, is an absolute absence of attributes, and so is Nought. Hence, the distinction between the two is only meant to be; it is quite a nominal distinction, which is at the same time no distinction. . . . Nothing, if it is thus immediate and equal to itself, is also conversely the same as Being is. . . . In Being we have Nothing, and in Nothing Being.... In Becoming the Being which is one with Nothing, and the Nothing which is one with Being, are only vanishing factors; they are and they are not."¹⁵

It is *Becoming* that constitutes the all-important process of evolution for Being. "Becoming is the first concrete thought, and therefore the first notion: whereas Being and Nothing are empty abstractions."¹⁶ Through this process of Becoming indeterminate Being becomes 'determinate Being.' Hegel gives the following account of Becoming. "Even our ordinary conception of Becoming implies that somewhat (something) comes out of it, and that Becoming therefore has a result. . . .Becoming always contains Being

and Nothing in such a way that these two are always changing into each other, and, reciprocally cancel each other. Thus Becoming stands before us in utter restlessness — unable, however, to maintain itself in this abstract restlessness: for since Being and Nothing vanish in Becoming (and that is the very notion of Becoming), the latter must vanish. . . . The result of this process, however, is not empty Nothing, but Being identical with the negation — what we call Being Determinate (being then and there): the primary import of which evidently is that it *has become*.”¹⁷

Since Being is Idea and Idea Being, it is by means of the logical process of Becoming that the Being-Idea gradually and successively passes from a state of indeterminateness to the determinateness of all beings, evolving progressively into nature (the world) and spirit (consciousness), until it finally harmonizes all differences of being in the Absolute Spirit. In this manner Hegel attempts to reduce all unity and plurality, all identity and change, to the supreme self-differentiating unity of the Absolute Idea-Being. Unity essentially involves diversity and self-negation, and it is this ‘power of negativity’ (*Macht der Negativität*) which is the eternal driving urge of self-evolution in the Absolute.

As the final result of this self-actualization of Being-Idea, all beings and all selves are but modes and manifestations of the Absolute. There is, of course, no creation. All finite things are but the ‘expression,’ the ‘appearance’ of the Absolute; the absolute becomes all things in a process of logical necessity. There is *no thing-in-itself* distinct from the all-inclusive reality of the Absolute. All dualism between

thought and thing is obliterated, and man and the world possess no 'otherness' of their own: all is 'thought realized.'

Most philosophers, Descartes and Kant included, maintained the essential dualism of thought and thing, subject and object, mind and matter, spirit and nature, God and world, real and ideal; even though they confused some of these opposites, they upheld the distinction in others. But Fichte, Schelling, Hegel, and their followers, eliminated this dualism and asserted the *one-ness* of all things in the Absolute: they defended the doctrine of *idealistic, pantheistic monism*. In the field of knowledge this involved an *epistemological monism* — the doctrine of the identity of thought with the object of thought.

The ultra-spiritualistic tendency of Descartes' principles here reached its ultimate peak of development. Kant and Hegel, particularly the latter, exerted a tremendous influence on subsequent philosophy. For decades Hegel's idealism held complete sway. Not to be a Hegelian was, for a long time, a sign of obscurantism. Eventually, however, some philosophers refused to follow these thinkers into the speculative clouds of Absolutism and preferred to remain closer to the homely soil of the earth. A reaction set in toward the more human philosophy of *realism*.

SUMMARY OF CHAPTER VII

A number of modern theories have arisen in an attempt to solve the problem of sense-knowledge.

1. *Descartes' Ultra-Spiritualism.* *Descartes* defined the mind as 'thought' and matter (body) as 'extension.' There is no real cognitional interaction between mind and body in man, because their disparity is too great; the body is a mere automaton, and all knowledge is potentially innate in the mind. The mind can know nothing but its own conscious states.

2. *Occasionalism, Ontologism.* *Geulincx* and *Malebranche* maintained that God produced all knowledge in the mind on the occasion of stimuli in the body. *Malebranche* also defended the ontologistic view that man's mind has an intuition of God's ideas and thus comes to know the world outside.

3. *Spinozism, Monadism.* *Spinoza* asserted the one-ness of mind and matter in the infinite substance of God; this infinite substance has 'extension' and 'thought,' so that the world and the mind are but two determinations of God.

According to *Leibnitz*, the ultimate beings are monads. There is no interaction between monads. All knowledge in monads is innate; it corresponds with reality, due to a pre-established harmony.

4. *Empiricism, Psychological Idealism.* *Locke* maintained that all knowledge comes from experience, and it is restricted to conscious states. We can know nothing of material substances. *Berkeley* denied the existence of a

physical world; its 'being' is 'being perceived.' He is a psychological and acosmistic idealist.

5. *Pan-Phenomenalism*. *Hume* denied the existence of all substance. All we can know are phenomena. He was a subjectivist and skeptic.

6. *Transcendental Idealism*. *Kant* claimed that some elements of our sense-knowledge are a posteriori, derived from experience, while others are a priori, derived from the mind anterior to all experience. Sense-perception is the result of the empirical element of sensations and the mental element of subjective, innate 'forms.' The noumena or things-in-them-selves excite sensations, producing the 'intuition' of an object; the object of this intuition is the *phenomenon*. 'Space' and 'time' are not qualities of bodies; they are *a priori forms* making perception possible by arranging the manifold of sense in the order of extension and succession (space and time). Noumena actually exist, but we can have no knowledge of them; our knowledge is limited to phenomena and as such has only subjective value.

7. *Absolutism*. *Fichte* endeavored to dissolve the antithesis between mind and matter by identifying all reality with the Ego: thought is the ultimate and only reality. By 'Ego' he means the universal consciousness of the Absolute. *Schelling* also identified the real and the ideal with the Absolute; mind and matter proceed from the indeterminateness of the Absolute, constituting its two phases. *Hegel* substituted 'immanent activity' for the 'indeterminateness' of the Absolute and made the Absolute or Being-Idea evolve by means of a purely logical and rational process of thought into the real (world) and the

ideal (mind), synthesizing everything in the Absolute Spirit. Absolutism is pantheistic idealism.

The ultra-spiritualistic principles of Descartes were thus developed into Absolutism.

Chapter 8

RETURN TO REALISM

IT WAS BUT NATURAL THAT A REACTION WOULD SET IN AGAINST THE exaggerated spiritualism of some of Descartes' principles. Locke and Hume insisted strongly on the role of the senses in the acquisition of knowledge. After all, it is hard for men, even if they be philosophers, to rid themselves of the conviction that the external world is real and that, somehow, we can and do perceive the world as it is. Later on, the extreme ideal-ism of the transcendentalists also brought about a reaction toward realism.

Locke had opposed the innateness of sense-perception as defended by Descartes, whereby the latter identified it with 'thinking'; but Locke went to the other extreme by debasing 'ideas' more or less to sense-impressions. Hume finished by reducing all ideas to a sense-knowledge of phenomena. Herein lay the seeds of sensism, positivism, and materialism.

SENSISM, POSITIVISM, MATERIALISM

Thomas Hobbes (1588—1679) was a confirmed materialist and sensist. The Abbé Condillac (1715—1780) made

sensation the sole source of all knowledge, so that all operations of the soul—judgment, reflection, and emotion — are nothing but 'transformations of sensation.' He did not deny the immateriality of the soul, but he considered consciousness itself to be but a form of sensation. Other representatives of the movement were *John S. Mill*, *Alexander Bain*, and *James Sully*.

Positivism owes its origin to *Auguste Comte* (1798—1857). Positivism identifies knowledge with empirical, *physical science*. We can know nothing but facts and the relations of facts. Only natural phenomena of matter and force, and the laws governing them, form the subject matter of positive science, and these alone are the objects of man's knowledge. Sensation is the only source of this knowledge; all else is futility and illusion. Positivism is the philosophic doctrine of many scientists. Modern defenders are: Spencer, Huxley, Tyndall, Congreve, Beesly, Allen, Bridges, Ribot, Ardigo, Laas, and Riehl.

Sensism was bound to end in materialism. Its main protagonists were *Karl Vogt* (1817—1895), *Jakob Moleschott* (1822—1893), *Ludwig Büchner* (1824—1899), and *Ernst Haeckel* (1834—1919). The only reality which exists is matter and mechanical motion; the mind is but a form of matter, and knowledge but a form of motion. Descartes' mechanistic interpretation of the human body and its relation to the mind hereby reached its lowest level; it is the extreme opposite of the idealistic pantheism attained in Hegel's philosophy. *Idealistic monism* and *materialistic monism* are the two epistemological poles of

modern philosophy, the logical result of Descartes' ill-fated antithesis between mind and body.

NATURAL REALISM, TRANSFIGURED REALISM

In opposition both to Humian skepticism and Kantian transcendentalism, the Scottish School reverted to *natural realism*. *Thomas Reid* (1710—1796) defended the immediate perception of external things; yet, oddly enough, he asserts that we are not conscious of this perception. James McGosh and T. Case were defenders of a realism very similar to that of Reid.

Sir William Hamilton (1788—1856), though a follower of Reid, was strongly influenced by Kantian ideas and maintained that we can know nothing but the *relative and phenomenal*. He accepts “the great axiom that all human knowledge, consequently that all human philosophy, is only of the relative and phenomenal. In this proposition, the term *relative* is opposed to the term *absolute*; and, therefore, in saying that we know only the relative, I virtually assert that we know nothing absolute, — nothing existing absolutely; that is, in itself and for

Itself, and without relation to us and our faculties. . . . Thus, mind and matter, as known and knowable, are only two different series of phenomena or qualities; mind and matter, as unknown and unknowable, are the two substances in which these two series of phenomena or qualities are supposed to inhere. The existence of an unknown substance is only an inference we are compelled to make, from the existence of known phenomena. ... Our

whole knowledge of mind and matter is thus, as we have said, only relative; of existence, absolutely and in itself, we know nothing."¹ He is, therefore, a *reasoned realist, but a relativist and phenomenalist*.

Herbert Spencer (1820—1903) was a naturalistic evolutionist. There exists an objective reality which is extra-mental, otherwise we cannot account for the 'persistence' and the 'definite character' of our sense-perceptions. This reality is the cause of our sensations. We cannot, however, go beyond the phenomena of things and know what the *ultimate reality* is like: the ultimate reality in nature is forever unknown and unknowable. We know 'that' it is, but we do not know 'what' it is. We think of reality in the terms of God, soul, mind, space, time, matter, motion, force, and similar ideas, but these are only symbols of the underlying reality, totally unlike the objects they represent. Spencer is, therefore, a *hypothetical realist and dualist*, but also a *phenomenalist*.

"The reality underlying appearances is totally and forever inconceivable to us."² "Ultimate religious ideas and ultimate Scientific ideas, alike turn out to be merely symbols of the actual, not cognitions of it. . . .The reality existing behind all appearances is, and must ever be, unknown."³ "Admitting, or rather asserting, that knowledge is limited to the phenomenal, we have, by implication, asserted that the sphere of knowable is co-extensive with the phenomenal co-extensive with all modes of the Unknowable that can affect consciousness."⁴

"Though Space, Time, Matter, and Motion are apparently all necessary data of intelligence, yet a psychological

analysis shows us that these are either built up of, or abstracted from, experiences of Force. . . Force, as we know it, can be regarded only as a certain conditioned effect of the Unconditioned Cause — as the *relative reality* indicating to us an Absolute Reality by which it is immediately produced. And here, indeed, we see even more clearly than before, how inevitable is that *transfigured realism* to which skeptical criticism finally brings us around.”⁵ And thus, the ultimate data of our knowledge are effects (phenomena) produced in our consciousness by some unknown cause (noumenon); the phenomena are the ‘symbols’ of this unknown ultimate reality, but the ‘symbols’ give us no likeness whatever of the things-in-themselves. This is an agnostic idealism, similar to Kant’s, but without Kant’s ‘mental forms.’

POST-KANTIAN REALISTIC TRENDS

Kant was not able to overcome Hume’s agnosticism. Since the outcome of his philosophy was that we can know only phenomena but never the noumena (things-in-themselves), his agnosticism was as pronounced as Hume’s. He indeed admitted the existence of things-in-themselves, but that was a mere postulate, an assumption. Some of his followers, dissatisfied with this conclusion, attempted to bridge the gap between phenomena and noumena. They desired to show that we could acquire some knowledge of what the thing-in-itself really is. Prominent among these are *F. H. Jacobi* (1743—1819), *J.F. Fries* (1773—1843), *J. F. Herbart* (1776—1841), *E. Husserl*, and *A. Meinong*.

Jacobi claimed that we can attain to a knowledge of supra-sensible reality, such as God and the soul, by means of a rational intuition of faith (*Gefühlsglaube*). Fries maintained that we have a 'presentment' (*Ahnung*) of the suprasensible in the sensible. Herbart looked for a speculative knowledge of the thing-in-itself in a rational criticism of the phenomena. If we analyze the Ego and the thing-in-itself we arrive at a multiplicity of 'reals' (*Realen*). Ultimately, therefore, nature consists of 'reals'; they are somewhat similar to the Leibnitzian monads, but they possess no power of representation and they have no activity except the power of self-preservation. While we have no experience of these 'reals,' the presence of phenomena prove their existence. Herbart's realism represents an approach to modern realistic philosophy. Husserl's and Meinong's 'objects' are not existential, but rather logical realities. These thinkers could not break through the phenomenalism of Kant; their doctrines form a system of logical realism which is at bottom a disguised logical idealism. However, their views greatly influenced contemporary realists.

NEO-ABSOLUTISM

Kant, while an idealist, maintained the essential difference between phenomena (appearances) and noumena (things-in-themselves), as distinct parts in our universe; he was a hypothetical dualist. Fichte, Schelling, and Hegel removed this essential difference between the 'subject' and 'object' in knowledge and made both *immanent* within knowledge,

thereby identifying both 'subject' and 'object,' mind and universe, in a common and single ground, the Absolute. The Absolute is an Organic Whole, a Unity-in-Difference, absorbing and harmonizing all reality. Such is the idea underlying Hegelian Absolutism.

A. *Schopenhauer* (1788—1860) and E. *von Hartmann* (1842—1906) conceived the Absolute in a different manner. Schopenhauer was a voluntarist. Instead of the Idea being the ultimate root of all reality, it is the Will. It is as much the Absolute as Fichte's Ego and Hegel's Being-Idea. The universe is but an objectification of the Will, and the essence of the world consists in a blind impulse, an unconscious, irrational striving of the Absolute Will in an eternal struggle for existence.⁶ Von Hartmann attempted a reconciliation of Hegel's idealism and Schopenhauer's voluntarism. The Absolute is the Will, but it is guided by ideas; since, however, it is not aware of this, it is unconscious. The Absolute, therefore, is the Unconscious.⁷

Neo-Hegelians subscribe to the general principles of Hegel; they differ, however, in their methods of approach and in minor points of doctrine. It is characteristic of these philosophers that they approach their problem through *experience* rather than by means of aprioristic speculations.

F. H. *Bradley*, for instance, begins with the obvious data of the qualities of bodies and attempts to show that they are unreal. He then takes substance and accident, relation and quality, space and time, motion and change, causation and activity, things and self, and comes to the general conclusion that our ideas of their nature are 'unintelligible,' self-contradictory, and full of inconsistencies. As far as we

know the universe, it is a mass of contradictions and appearances. But these appearances must be a qualification of reality in some way, and the contradictions must be overcome in a higher unity. This is done in the Absolute. "Everything phenomenal is somehow real; and the absolute must at least be as rich as the relative. And, further, the Absolute is not many; there are no independent reals. The universe is one in this sense that its differences exist harmoniously within one whole, beyond which there is nothing. Hence the Absolute is, so far, an individual and a system. . . . The Absolute is one system, and *its contents are nothing but sentient experience*. It will hence be a single and all-inclusive experience, which embraces every partial diversity in concord. For it cannot be less than appearance, and hence no feeling or thought, of any kind, can fall outside its limits"⁸ "The Absolute is not personal, nor is it moral, nor is it beautiful or true. . . . The Absolute stands above, and not below, its internal distinctions. It does not eject them, but it includes them as elements in its fullness. To speak in other language, it is not the indifference but the concrete identity of all extremes. But it is better in this connection to call it super-personal."⁹

According to *T. H. Green*, "the terms 'real' and 'objective' have no meaning except for a consciousness which presents its experiences to itself as determined by relations, and at the same time conceives a single and unalterable order of relations determining them. . . . When we analyze our ideas of matter of fact, can we express it except as an idea of a relation which is always the same between the same objects; or our idea of an object except

as that which is always the same in the same relation? And does not each expression imply the idea of a world as a single and eternal system of related elements, which may be related with endless diversity but must be related still? If we may properly call the consciousness which yields this idea 'understanding,' are we not entitled to say that understanding is the source of there being for us an objective world, that it is the principle of objectivity."¹⁰ "The concrete whole, which may be described indifferently as an eternal intelligence realized in the related facts of the world, or as a system of related facts rendered possible by such an intelligence, *partially and gradually reproduces itself in us*, communicating piece-meal, but in inseparable correlation, understanding and the facts understood, experience and the experienced world."¹¹ And thus the knowing subject and the known object, the ideal and the real, the self and the world, are but the distinct realizations of the 'eternal intelligence,' or Absolute, reproducing itself in finite forms.

Other philosophers, who belong more or less to this class, are W. Wallace, J. H. Stirling, I. Caird, E. Caird, J. Watson, J. Royce, B. Bosanquet, A. E. Taylor, W. E. Hocking, W. T. Harris, B. Croce, O. Gentile, J. A. Leighton, M. W. Galkins, A.S. Pringle-Pattison, R. F. A. Hoernlé, F. Paulsen, W. Windelband, H. Rickert, H. Münsterberg, F. Münch, H. Cohen, P. Natorp, E. Cassirer.

NEO-PSYCHOLOGISM

Neo-Psychologism is the outcome of a closer union between empirical science and psychology. Psychological idealism maintains in general that things depend for their existence on being perceived by the mind or in consciousness; their 'being' is 'being perceived,' and they are, therefore, non-existent except as 'ideas.' Berkeley and Hume were exponents of this doctrine. The neo-psychologists, however, are influenced by other systems of thought, which modify the general theory. Neo-psychologism attempts to bridge the gap between mind and matter by applying the principles of empirical science to consciousness; it thus represents a step away from idealism and an *approach toward realism*.

According to *J. H. Poincaré*, all external objects are but sensation-complexes united together by relations. Since we can only think of thoughts, thought is all that exists, and all that is not thought is pure nothingness. Later on his tendency was more toward realism. To *E. Mach* the Ego is a mass of sensations in coherence; bodies are groups of sensations; there are no material realities corresponding to our ideas of objects like atoms and molecules; everything is at the same time physical and psychical, so that there is no fundamental difference between the 'real' and the 'experience.' *R. Avenarius*, in his 'empirio-criticism,' also assumes as his starting point the principle that nothing exists save experience. All our perceptions are subjective; they do not reveal to us the external objects themselves. Logically his principles lead to subjectivism and materialism.

W. Wundt in his 'ideal-realism,' takes a stand midway between idealism and realism; as a scientist he leaned toward realism, and as a Kantian he could not free himself from idealism. His 'theory of actuality' denies the existence of all substance: "The contents of psychological experience should be regarded as an *interconnection of processes*. This concept of process excludes the attribution of an objective and more or less permanent character to the content of psychical experience. Psychical facts are *occurrences*, not objects."¹² The concept of "mind-substance' has no value except to satisfy "a mythological and metaphysical need."¹³ There is nothing but a manifold of interrelated occurrences, an inner (psychical) and outer (physical) experience. This is the system of a *psycho-physical parallelism*.

There is no completely uniform body of doctrine among any set of idealists. However, the general trend of their ideas warrants the placing of the following thinkers in this group: W. K. Clifford, Karl Pearson, H. R. Marshall, G. S. Fullerton, S. H. Hodgson, J. H. Muirhead, D. G. Ritchie, J. Petzoldt, T. Lipps, H. Vaihinger, A. Fouillée, H. Bergson, C. Renouvier.

PERSONALISM

A new philosophic movement is coming to the front in our day. It is closely allied to classic idealism, yet seeks to avoid the absolutistic implications of the latter. In general, it is more voluntaristic than intellectualistic, and it is more in accord with the traditional idea of God than with the pantheistic notion of the Absolute. There are in it, however,

many odd and conflicting elements, which time will have to sift and eliminate, before it can reach a final stage of clarification.

Some forms of personalism are *non-typical* and hardly deserve the name. The personalism of J. M.E. McTaggart (1866—1925) is atheistic; that of Wilhelm Stern is pantheistic: that of C. Renouvier (1815—1903) is relativistic; that of E. Caird, J. Royce, and Sir Henry Jones is absolutistic; and that of G.W.

Howison, W. Vatke, and H. W. Carr is teleological (i.e., God is not the First Cause or creator of the universe, but its Final Cause or goal).

Typical personalism is theistic; it accepts a *personal God* and seeks the ultimate explanation of all things in Him. From this standpoint it differs radically from the non-typical forms of personalism just mentioned. God is the creator of the universe, and this point distinguishes personalism from the systems of Spinozism and Hegelianism. In epistemology it favors dualism rather than monism; there is a real distinction between thought and thing. Personalism, on the other hand, contends that whatever is ontologically real can be found only in personality. Personalism is also more voluntaristic than traditional theism. The will counts more than the intellect. A cogent rational demonstration of God's existence is impossible; our acceptance of His existence rests ultimately on faith, not on reason. And faith, not reason, is the foundation of all philosophy. The reality of the soul or self as a 'person' is of the very essence of personalism; but the soul is, as a rule, considered to be

rather a 'power of action' than a real substance. Most personalists lean toward occasionalism.

Albert C. Knudson gives the following definition of personalism: "We may define personalism as that form of idealism which gives equal recognition to both the pluralistic and monistic aspects of experience and which finds in the conscious unity, identity, and free activity of personality the key to the nature of reality and the solution of the ultimate problems of philosophy."¹⁴ Among the main representatives of the philosophy of personalism Knudson mentions *H. Lotze* (1815—1881), *A. C. Fraser* (1819—1914), *J. Ward* (1843—1925), *A. J. Balfour*, *A. S. Pringle-Pattison*, *J. C. Wilson* (1849–1915), *H. Rashdall* (1858—1924), *W. R. Sorley*, *C. C. Webb*, *R. Eucken* (1846—1926), *G. T. Ladd* (1842—1921), and *Borden P. Bowne* (1847—1910). Of these, Bowne is undoubtedly the most outstanding proponent of the new philosophy.

From the above it will be clear that personalism is far from being a definitely finished and cohesive system. Bowne has this to say of himself: "It is hard to classify me with accuracy. I am a theistic idealist, a Personalist, a transcendental empiricist, and idealistic realist, and a realistic idealist; but all these phrases need to be interpreted. They cannot well be made out from the dictionary. Neither can I well be called a disciple of anyone. I largely agree with Lotze, but I transcend him. I hold half of Kant's system, but sharply dissent from the rest. There is a strong smack of Berkeley's philosophy, with a complete rejection of his theory of knowledge. I am a *Personalism*, the first of the clan in any thoroughgoing sense."¹⁵ Bowne

was the systematizer of personalism. He improved on Lotze by introducing “as an essential and controlling factor the thought of *free* self-activity. . . Bowne made freedom the touchstone of reality.”¹⁶ Personalism, it seems, may be destined to help some devotees of idealism find their way back to theism.

PRAGMATISM, HUMANISM

Pragmatism and humanism are a strong repudiation of Kantian rationalism and Hegelian absolutism. They propose to take man down from the clouds of intellectual abstraction from the “supercelestial heavens of Pure Reason,” and it is their “avowed aim of *humanizing* Truth and bringing it back to earth from such altitudes.”¹⁷ Pragmatism originated as a modern theory of knowledge with *Charles S. Peirce* in 1878, and its chief exponents are *William James*, *F. C. S. Schiller*, and *John Dewey*. Pragmatism and humanism are so closely akin that they can be considered one, the latter being an extension and an expansion of the former. Schiller explains the relation between the two: “Pragmatism will seem a special application of humanism to the theory of knowledge. But humanism will seem more universal. It will seem to be possessed of a method which is applicable universally, to ethics, to aesthetics, to metaphysics, to theology, to every concern of man, as well as to the theory of knowledge.”¹⁸ Both are therefore identical in principle and are more or less interchangeable terms.

Pragmatism is a return to *empiricism* and a protest *against apriorism*. As James puts it: “Pragmatism

represents a perfectly familiar attitude in philosophy, the empiricist attitude, but it represents it, as it seems to me, both in a more radical and in a less objectionable form than it has ever yet assumed. A pragmatist turns his back resolutely and once for all upon a lot of inveterate habits dear to professional philosophers. He turns away from abstraction and insufficiency, from verbal solutions, from bad a priori reasons, from fixed principles, closed systems, and pretended absolutes and origins. He turns towards concreteness and adequacy, towards facts, towards action and towards power. That means the empiricist temper regnant and the rationalist temper sincerely given up. It means the open air and possibilities of nature as against dogma, artificiality, and the pretence of finality in truth. At the same time it does not stand for any special results. It is a method only. . . . Being nothing essentially new, it harmonizes with many ancient philosophic tendencies. It agrees with nominalism for instance, in always appealing to particulars; with utilitarianism in emphasizing practical aspects; with positivism in its disdain for verbal solutions, useless questions and metaphysical abstractions. . . . No particular results then, so far, but only an attitude of orientation, is what the pragmatic method means. *The attitude of looking away from first things, principles, 'categories,' supposed necessities; and of looking towards last things, fruits, consequences, facts.*"¹⁹

The truth is 'made' by means of postulate and experiment, so that something is 'true' if it satisfies some human need of ours and 'false' if it does not. "Pragmatism," says Schiller, essays to trace the actual 'making of truth,'

the actual ways in which discriminations between the true and the false are effected, and derives from these its generalizations about the method of determining the nature of truth. It is from such empirical observations that it derives its doctrine that when an assertion claims truth, *its consequences are always used to test its claim*. In other words, what follows from its truth for any human interest, and more particularly in the first place, for the interest with which it is directly concerned, is what establishes its real truth and validity. . . . Human interest, then, is vital to the existence of truth: to say that a truth has consequences and that what has none is meaningless, means that it has a bearing upon some human interest. Its 'consequences must be consequences to some one for some purpose.'²⁰

Truth is nothing permanent, necessary, universal, objective, absolute; it is relative, transient, particular, subjective, personal. If an idea, judgment, assumption, axiom, postulate, theory, or system of thought 'works' and satisfies our mental or emotional or social needs, *it is, so far and so long as it does this*, valuable and 'true.'

"True ideas are those that we can assimilate, validate, corroborate and verify. False ideas are those that we cannot. That is the practical difference it makes to us to have true ideas; that, therefore, is the meaning of truth, for it is all that truth is known as.

"This thesis is what I have to defend. The truth of an idea is not a stagnant property inherent in it. Truth happens to an idea. It becomes true, is made true by events. Its verity is in fact an event, a process: the process namely of its

verifying itself, its verification. Its validity is the process of its *validation*.”²¹

John Dewey stressed the *instrumentalism* of knowledge. Thinking is a biological function; consequently ideas are only instruments for interpreting and arranging experience, and the mind is only an instrument for controlling the environment. The theory is an application of the principle of evolution to the function of thought.²²

Henri Bergson, though actually a vitalistic idealist in his general doctrine, must be placed among the pragmatists so far as his *intuitionism* is concerned. Evolution has developed consciousness in two opposing directions: intellect and intuition. “Intelligence, by means of science, which is its work, will deliver up to us more and more completely the secret of physical operation. . . . But it is to the very inwardness of life that *intuition* leads us — by intuition I mean instinct that has become disinterested, self-conscious, capable of reflecting upon its object and of enlarging it indefinitely.”²³ The intellect can give us only static pictures, ‘snapshots,’ ‘cinematographical views,’ of reality. Reality is in a process of perpetual change; knowledge, therefore, is forever in the making, and it is intuition which reveals to us the inner nature of reality. “On our personality, on our liberty, on the place we occupy in the whole of nature, on our origin and perhaps also on our destiny, it throws a light feeble and vacillating, but which none the less pierces the darkness of the night in which the intellect leaves us.”²⁴ Intuition is better than intellect.

Hans Vaihinger defends a theory of *fictionalism*. All concepts are fictions of the mind; they have a certain

amount of fictional value as mental constructions of reality, but though they 'work' in this respect they need not be true in themselves. Concepts are only means toward the end of adapting ourselves to our environment; as such they possess only a provisional character.²⁵

Another offshoot of pragmatic thought is the *imaginism* of *Douglas Fawcett* and a few others. Along lines similar to the universal consciousness of idealists, Fawcett considers 'imagination' to be the creative force of all reality. This cosmic imagining is a conscious infinite activity. Human thought is purely instrumental, necessary for adjustment to environmental conditions.²⁶

J. M. Baldwin advocates an esthetic pragmatism, which he calls *pancalism*. *Maurice Blondel*, one of the founders of modernism, propounds a form of religious pragmatism. E. LeRoy combines religious pragmatism with Bergsonian philosophy; scientific laws are mere instruments of practical life, not true expressions of reality.

A number of pragmatists have expressed their views conjointly in a volume, applying the doctrine to various departments of knowledge. The authors are: J. Dewey, A. W. Moore, H. C. Brown, G. H. Mead, H. W. Stuart, J. H. Tufts, H. M. Kallen, B. H. Bode. The book is entitled *Creative Intelligence*.²⁷

NEO-REALISM

In 1910 there appeared the 'Program and First Platform of Six Realists,' and in 1912 these six collaborators published their views in a joint volume, *The New Realism*.²⁸ The

authors were *Edwin B. Holt, Walter T. Marvin, Will. P. Montague, Ralph B. Perry, Walter B. Pitkin, and Edward G. Spaulding*. Though they disagree in details, their fundamental tenets are the same.

The essential issue of this new realism is outlined as follows:

"The escape from subjectivism and the formulation of an alternative that shall be both remedial and positively fruitful, constitutes the central prominent issue of any realistic protagonist. . . . The new realists' relational theory is in essentials very old. To understand its meaning it is necessary to go back beyond Kant, beyond Berkeley, beyond even Locke and Descartes — far back to that primordial common-sense which *believes in a world that exists independently of the knowing of it*, but believes also that that same independent world can be *directly presented* in consciousness and not merely represented or copied by 'ideas.' In short, the new realism is, broadly speaking, a return to naive or natural realism."²⁹

In their endeavor, though, to avoid subjectivism and exaggerated dualism, the neo-realists have gone to the opposite extreme. Instead of identifying external, material objects with the conscious states of the knowing mind, they practically identify mind, consciousness, and Ego with these objects. There are no substances. "I believe," says Holt, "that no knower, or Ego, such as metaphysics means, exists."³⁰ The world is a four-dimensional (spatio-temporal) manifold of 'quality-groups.'³¹ This is, of course, very much like Hume's phenomenalism. Perry is in accord with this view: "Modern realism is closer to the monistic realism of

‘ideas,’ suggested by Hume, than to the dualistic realism of mind and matter, propounded by the Scottish School; and this in spite of the fact that the Scottish philosophy was primarily a polemic, in the name of ‘realism,’ against Hume, as the last and most outrageous of the idealists. The new realism, while it insists, as all realism must, that things are *independent*, asserts that when things are known, they are ideas in the mind. They may enter *directly into* the mind; and when they do, they become what are called ‘ideas.’ So that ideas are only things in a certain relation; or, things, in respect of being known, are ideas.”³² “‘Epistemological monism’ means that when perceived, things are directly and identically present in consciousness.”³³

How can things be directly and identically present in consciousness? Because consciousness is really identical with the things themselves in nature. As Perry expresses himself: “The difference between knowledge and things, like that between mind and body, is a relational and functional difference, and not a difference of content.”³⁴ Or, as Holt puts it: “We have become wedded or indeed welded to the phrase — my thought is of an object, when we ought to say and mean — my thought is a portion of the object — or better still, — a portion of the object is my thought: — exactly as a portion of the sky is the zenith.”³⁵ The ‘mind’ is identical with the nervous system, and ‘thinking’ is a function of it. The mind is thus eliminated as a distinct entity and with it the ‘knower’; all that remains is the ‘object’ and the process of ‘knowing.’ Knowing, therefore, and consequently also ‘consciousness,’ must be a relation or modification of the objects themselves.³⁶ Montague calls

this doctrine *hylopsychism* and explains: "By hylopsychism I wish to denote the theory that all matter is instinct with something of the cognitive function."³⁷ Since all matter is thus 'instinct with something of the cognitive function,' it is obvious that the psychical and physical, mind and matter, are ultimately the same reality. And since the neo-realists always insist that the material objects are real, it follows that mind is reduced to matter. This is plain phenomenalist materialism. The 'epistemological monism' of neo-realism thus ends in *materialistic monism*.

Not all neo-realists subscribe to all the views outlined above. The English neo-realists, like *G. E. Moore*, *B. Russell*, *S. Alexander*, *T. Nunn*, and others, are somewhat more conservative. Within the general framework of this epistemological monism they differ very much among themselves. Since, however, all seem to agree that consciousness is merely a modification of the objects themselves, neo-realism is *pan-objectivism*.

CRITICAL REALISM

As in the case of neo-realism, a group of 'programmists' launched critical realism in 1916 — *D. Drake*, *A. O. Lovejoy*, *J. B. Pratt*, *A. Rogers*, *G. Santayana*, *R. W. Sellars*, and *C. A. Strong*. In opposition to idealism and subjectivism they all maintain the existential independence of physical objects from consciousness and the mind. They all agree, however, that the secondary qualities of colors, sounds, and the like, are not present in the objects as they appear in perception; they are subjective, though causally produced by external

objects in the organism. Their treatment of the primary qualities of extension, motion, and so on, is not so clear and uniform.

Since the fundamental trend of critical realism is *materialistic* and *evolutionary*, mind and consciousness are ultimately reducible to 'brain-events' and to a 'functional variant' of the nervous system.³⁸ Drake believes in *pan-psychism*: "The term pan-psychism' may properly be applied to our theory; but we must understand that it is only mind-stuff that is universal, not mind itself. The attribution of quasi-human forms of consciousness to the inorganic world is poetic and fanciful, not at all an implication of our view. The whole world is indeed, in a sense, alive. But it does not know itself to be alive. . . . We are therefore free to believe that the *stuff* that is deployed in this or that order throughout the universe is the same sort of stuff that composes us, sentient beings that we are. . . . Our theory puts an end to the need of introducing such magical entities as 'souls' or 'entelechies,' and (as we shall see) explains consciousness in natural terms."³⁹

In describing the process of sense-perception, critical realists use a terminology of their own. The elements involved are thus described by Strong: "By 'object' I mean the real thing, existing in one continuous space and one continuous time. An essence' is anything that can be given, whether to sense-perception or to thought, considered not as given but simply in itself. A 'datum' is an essence considered as given. 'Consciousness is the function by which things are given — i.e., the same as 'awareness' or 'givenness.' The 'Ego,' or 'self,' is the being (located in or

the substance of the organism) to which things are given. By 'psychic state,' finally, I mean the concrete state of the self which makes it possible for things to be given, or a similar state. . . . Of these the two most important are (1) that what is given in sense-perception is not the object as an existence, but only the object as an essence, (2) that in addition to the essence no givenness is given. So that, on both grounds, the datum of sense—perception is a bare essence"⁴⁰

To understand what Strong means by the term 'essence,' we must go to Santayana, who introduced it into epistemology as a factor in sense-perception. It is "a universal, of any degree of complexity and definition, which may be given immediately, whether to sense or to thought. Only universals have logical or aesthetic individuality, or can be given directly, clearly, and all at once."⁴¹ "That which appears, when all gratuitous implications of a world beyond or of a self here are discarded, will be an *essence*."⁴² "The inalienable individuality of each essence renders it universal; for being perfectly self-contained and real only by virtue of its intrinsic character, it contains no reference to any setting in space or time, and stands in no adventitious relations to anything. . . . After things lose their existence, or before they attain it, although it is true of them that they have existed or will exist, they have no internal being except their essences, quite as if they had never broached Existence at all: yet the identity of each essence with itself and difference from every other essence suffices to distinguish and define them all in eternity, where they form the Realm of Essence."⁴³ "The realm of essence, like the

empyrean, is a clear and tranquil region when you once reach it"⁴⁴

From all these characterizations of Santayana it is clear that essence is very much like the Universal Idea of Plato — a logical, ideal entity, which may or may not be embodied in physical things. This idea has been taken over into epistemology by the critical realists, though not always in this pure form. Strong, for instance, calls the ‘datum’ of sense-perception “the logical essence of the real thing. By ‘essence’ I mean its what divorced from its *that* — its entire concrete nature, including its sensible character, but not its existence.”⁴⁵ But Love-joy is opposed to these essences as ‘universals,’ when applied to physical ‘reals’ (objects), at least in the meaning that the senses can perceive these essences themselves.⁴⁶ Drake explains the matter this way: “Anything that *could* be imagined, or that might exist, any describable somewhat, is an ‘essence. . . Every particular existent is the existential embodiment of some particular essence. . . These ideas, essences, characters, logical entities, are merely possibilities of existence, and possibilities of discourse.”⁴⁷

Though the critical realists differ in their interpretation of the term ‘essence,’ they all agree that the ‘datum,’ or ‘essence,’ or ‘content,’ or ‘thing-experience,’ or ‘character’ (the terms mean the same thing), is the only thing which is intuited in perception. *The physical object itself is never perceived directly.* After all, then, the ‘datum’ is only a symbol of reality, and no one can be certain that the symbol adequately reveals the reality symbolized. Critical realism at best is a disguised form of *representative realism*.

EMERGENT EVOLUTION

Modern theories of realism are conjoined, as a rule, with the theory of evolution. From this combination there has arisen a new doctrine of realism, called evolutionary naturalism or *emergent evolution*. The basic idea is that nature is the product of evolution in such a manner that *entirely new and unpredictable properties* originate through synthesis and thereby form new and higher levels of reality. These new properties are not mere 'resultants' obtained by addition or subtraction from among previously existing properties; rather, these new properties have no counterpart in the lower levels and simply emerge' with specific characters not discoverable in the former (lower) levels.⁴⁸ W. McDougall characterizes emergence as follows: "It is claimed that each instance of emergence is creative of real novelty, of some new quality or property of type that did not exist before the emergence; that it is unpredictable before the event on the basis of any knowledge, matter how complete, of the things or events that enter into the synthetic event; that, because it is unpredictable, it is to be regarded as non-mechanistic; further, the new kind of relatedness, or the new quality or property, has causal efficacy, makes a difference to the further course of events."⁴⁹

According to S. Alexander the root of all things in evolution is Space-Time. "The world actually or historically develops from its first or elementary condition of Space-Time, which possesses no quality except what we agreed to call the spatiotemporal quality of motion. But as in the

course of Time new complexity of motions comes into existence, a new quality emerges, that is, a new complexity possesses as a matter of observed empirical fact a new or emergent quality."⁵⁰ In this manner all new levels of reality 'emerge': "Material things have certain motions of their own which carry the quality of materials. In the presence of light they are endowed with the secondary quality of color. Physical and chemical processes of a certain complexity have the quality of life. The new quality life emerges with this constellation of such processes, and therefore life is at once a physico-chemical complex and is not merely physical and chemical, for these terms do not sufficiently characterize the new complex which in the course and order of time has been generated out of them."⁵¹ *Mind* is also such an emergent: "Mind is a new quality distinct from life, with its own peculiar methods of behaviour."⁵²

Emergent evolution thus travels upward along the following lines: matter, life, mind, and (according to some) deity. Morgan represents the whole trend by means of a diagrammatic pyramid, whose base is space-time, and all emergents are built up from this base — "atom-pyramids near the base, molecules a little higher up, yet higher, things (e.g., crystals), higher still, plants (in which mind is not yet emergent), then animals (with consciousness), and near the top, our human selves."⁵³

Other emergentists are: *L. T. Hobhouse* (who seems to have relinquished his views later), *C. A. Strong*, *D. Drake*, *E. Noble*, *R. Sellars*,⁵⁴ but they disagree on certain vital points.⁵⁵ It will be noted that these philosophers attempt to bridge the gap between mind and matter by means of

‘emergence.’ The relation of this theory to the problem of knowledge is indirect; all emergentists are realists in explaining the process of cognition. Among biologists who favor the theory of emergent evolution one might mention H. F. Osborn, C. J. Herrick, H. S. Jennings, G.H. Parker, S. R. Lillie, W. M. Wheeler, W. E. Ritter, and others [Teilhard de Chardin, ed.].

OBJECTIVE RELATIVISM

Objective relativism (or, as William P. Montague⁵⁶ calls it, relativistic objectivism) attempts to harmonize two theories of knowledge which seem mutually exclusive: objectivism and relativism. Objectivism contends that things are, when not experienced by us, just what they seem when experienced by us. Relativism, on the other hand, maintains that every known object is relative (in relation) to the knowing subject and as such is dependent in its being upon the knowing subject and incapable of existing apart from consciousness. ‘Objective relativism,’ then, is the doctrine which holds that all perceivable objects are relative to the perceiver, so that they owe their nature and existence to the relations in which they stand to the perceiver; and this relativity is of such a character that the perceived objects (phenomena) are physically objective precisely as they appear in the act of perception, according to the standpoint of the individual perceiver.

This seems very obscure and complicated, but it is really quite simple. Three persons look at a penny from three different angles. The first sees it as a circle; the second sees

it as an ellipse; the third, looking at it edgewise, sees it as a straight thin line. Which of these three 'appearances' is the objectively true one? All three are; the penny is objectively and actually circular and elliptical and straight-lined, depending on the 'context' or 'experience-set' of the individual observer. Two persons look at a table top; one sees it as a square and the other as a rhombus. The table is really both a square and a rhombus at the same time. If a patient suffering from *delirium tremens* sees pink elephants and green monkeys, these animals are as real and genuine for him as those he sees in a zoological garden. What you perceive, that *is*. And as objects appear in perspective, that is what they *objectively are*. There is no objective difference between 'real' and 'unreal' appearances.

What, then, are the *objects*? Nothing but the 'aspects' of things seen in perspective. As *Bertrand Russell* says: "Instead of supposing that there is some unknown cause, the 'real' table, behind the different sensations of those who are said to be looking at the table, we may take the whole set of these sensations (together possibly with certain other particulars) as actually being the table. That is to say, the table which is neutral as between different observers (actual and possible) is the set of all those particulars which would naturally be called 'aspects' of the table from different points of view. . . . We have only, therefore, to notice how they [the particulars which are its aspects] are collected together, and we can keep the collection without assuming any 'real' table as distinct from the collection."⁵⁷ Or, as *Arthur E. Murphy* puts it: "The qualities are not the

existent, to be sure, but they are its whole nature, and it has no other.”⁵⁸

That objective relativism admits of no objective distinction between *reality and illusions or delusions* is clear from the following statement of A. N. Whitehead: “Pure presentational immediacy refuses to be divided into delusions and non-delusions. It is either all of it, or none of it, an immediate presentation of an external contemporary world as in its own right spatial.”⁵⁹ There is no difference between ‘delusions and non-delusions’; the former are as objectively real as the latter. What I perceive in nightmare dreams and fever hallucinations is no less real in the objective world than what I perceive in broad daylight when awake and normal.

This is the objective relativism of Whitehead, Dewey, Murphy, and others. It is a peculiar mixture of phenomenalism, subjectivism, objectivism, and neo-realism.

ARISTOTELIAN-SCHOLASTIC REALISM

Along with all these conflicting and confusing theories of knowledge, the age-old doctrine of *immediate perception* maintained its hold on the more conservative philosophers. It teaches that the spontaneous conviction of mankind is in general the correct view, and that we actually perceive the objects of the external world as they are in themselves. The senses do not merely ‘represent,’ they actually ‘present’ reality, at least in some form; man, therefore, does *not infer* the existence of objects ‘out there’ in nature from the existence of some ‘representative’ image in his

consciousness, but *perceives them directly through intuition*. As such, then, this theory subscribes to the doctrine of natural dualism and natural realism, at least in its main features. Ego and non-Ego, mind and matter, self and world, subject and object, consciousness and nature, psychical and physical, retain their respective individuality, distinct and unconfused, each in its own identity and being; this is natural dualism as opposed to monism and absolutism. The mind perceives the things of the external world directly in some form or other, so that the world is *immediately present* to the mind in the process of sense-perception without the perpetual intervention of a 'screen of representations,' and what the mind perceives in its intuition is not its own 'ideas' or subjective states but the *objects themselves*; this is natural realism as opposed to idealism and subjectivism.

The bridge between the world and the human mind is the *human body*. It is through the body and its senses and nervous system that external objects are able to contact the mind, and the mind is able to perceive the external objects. Since, however, the body is itself a part of the external world (as distinct from the mind), the only way in which the body can become the 'epistemological bridge' between the mind and the world, thereby making a direct perception of the world possible, is by entering into a distinct epistemological union with the mind: *mind and body must be an epistemological unit*. They must act together as the unit of perception. If each were divorced from the other, as postulated in the radical antithesis of Descartes, there would be no possibility of interaction between them, and

knowledge of the external world could never enter the mind. This Cartesian antithesis must, therefore, be a false conception. Mind and body must form one *organic whole*. Perception is a 'vital' function, but 'extended' in process; consequently neither the body alone nor the mind alone forms the adequate basis of perception, but the *animated organism of mind and body together*.

According to the general aristotelian-scholastic view, the material objects emit certain active energies (light, sound, heat, mechanical motion, etc.), and these energies affect the sense organs and nervous system, producing therein a *cognitional image* or likeness of the objects. This image is, of course, not a 'mirroring' or 'photographing' of the object upon the mind, but a vital *cognitional determinant* impressed upon sense-consciousness. The sense-consciousness responds in its own way to this determinant by becoming aware of the presented object. The mind is thus not conscious of this 'image' itself in the act of perception, but directly of the 'object'; the 'image' is merely the means by which the mind perceives the external reality.

Many modern scholastic philosophers, however, lean strongly in the direction of representative perception. They contend that this sensory 'image' becomes directly an object of awareness to the mind, and in it and from it the mind derives a sense-knowledge of material objects, instinctively referring these 'representations' to the things themselves. This would be mediate, not immediate, perception. They adhere to this view, because they are convinced that science has proved that objects are not always in nature as they appear to the senses; they claim

that the perceiving subject modifies the physical stimuli in its own characteristic manner (for instance, in color-vision, taste, etc.), so that the result is different from the condition of the objects as they are in nature. In this view all qualities of objects exist *formally in the subject and only causally in the objects*.

Other neo-scholastics, also influenced by the findings of science, defend the view that the facts prove that some perception (for instance, that of touch) is *immediate*, while other perceptions (for instance, those of color-vision, sound, flavor, taste, etc.) are *mediate* in character. In this view the fundamental sense of touch is the guarantee for the essential truth of the perception of extra-mental reality and serves as a check or control of the other perceptions. This theory is, therefore, partly 'presentative' and partly 'representative,' partly 'immediate' and partly 'mediate.' In any case, however, external reality is revealed to the mind through sense-perception.

Scholasticism combined within its system the best elements of the philosophy of Plato, of Aristotle, of the Neoplatonists, and of St. Augustine. In the main, however, it followed the teachings and principles of Aristotle. Scholasticism reached its highest development in the great minds of *St. Albert the Great* (1193 [or 1206]—1280), *St. Bonaventure* (1221—1274), *St. Thomas Aquinas* (1225—1274),⁶⁰ perhaps the most brilliant genius of synthesis who ever lived, and *John Duns Scotus* (1274 [or 1266]—1308). In the period of transition between medieval and modern scholasticism, the following names are noteworthy: *Thomas de Vio Cajetan* (1469—1534), *Toletus* (1532—1596),

Fonseca (1528—1599), *Vasquez* (1551—1604), *Suarez* (1548—1617), and *Sylvester Maurus* (1619-1687).

In general, *scholasticism* advocates a natural dualism of God and creature, mind and matter, thought and thing, as against monism and pantheism; it defends a moderate realism, as against ultra-realism, nominalism, and conceptualism, in the problem of the universals; it is spiritualistic and not materialistic, experimental and not aprioristic, objectivistic and not subjectivistic; in sense-perception it is presentational and not agnostic or representational or idealistic; concerning intellectual knowledge it defends a moderate rationalism, as against sensism, positivism, and innatism; it is common-sense knowledge critically examined and philosophically vindicated.

Neo-scholasticism is the renewal or revival of medieval scholasticism, adapting its fundamental principles and tenets to modern intellectual problems, remaining in close contact with the progress of the natural sciences and employing their legitimate findings as the basis for philosophical research. Neo-scholasticism had its beginnings in the middle of the nineteenth century, and since that time it boasts a long roster of prominent names in various countries.

In *Italy* we may mention *C. Sanseverino* (1811—1865), *J. M. Gornoldi* (1822—1892), *S. Tongiorgi* (1820—1865), *T. Zigliara* (1833—1893), *M. Liberatore* (1810—1892), *S. Schifflini* (1841-1906), *G. Bruni*, *A. Gemelli*, *P. Gény*, and *F. Olgiati*. In *Spain, Portugal*, and the Spanish-speaking countries: *James Balmes* (1810—1848), *Z. Gonzalez y Diaz*-

Tufion (1831—1892), J. M. Orti y Lara, A. Gomez Izquierdo, J. Urráburu, Teixeira Guedes, G. Garcia, E. Valverde Tellez. In *Germany, Austria, Poland, Switzerland*: J. Kleutgen (1811—1883), A. Stöckl (1823—1895), T. Pesch, J. Hontheim, C. Gutberlet, E. Commer, O. Willmann, J. Jungmann, V. Cathrein, M. Grabmann, A. Lehmen, F. Ehrle, C. Baeumker, J. Fröbes, B. Jansen, J. Geyser, E. Przywara, B. Switański, P. de Munnynck, P. Mandonnet, J. Donat. In France and Belgium: Domet de Vorges, P. Vallet, A. Farges, E. Blanc, P. Peillaube, A. Sertillanges, R. Garrigou Lagrange, J. Maritain, E. Gilson, L. de San, *G. Lahousse, D. Card. Mercier* (1851—1926), M. de Wuif, D. Nys, L. Noel, S. Deploige, R. Kremer, J. Maréchal, A. Michotte. In Hungary, Bohemia, and the Netherlands: Kiss, Pécsi, and Van de Groot. In *England, Ireland, and the United States*: T. Harper, John Rickaby, Jos. Rickaby, R. Clarke, B. Boedder, *M. Maher*, C. Devas, L. Walker, G. Joyce, M. D'Arcy, *P. Coffey*, M. Cronin, W. Poland, J. Driscoll, E. Pace, W. Turner, J. Ryan, F. Sheen, L. Ward, G. Esser, J. Zybura, T. Moore, H. Gruender, R. Bandas, J. Barron, J. McWilliams. Many more names could be added.

This brief survey of the systems which have originated in the course of the past three centuries, plainly shows the confusion of thought brought about by Descartes' ill-fated ultra-dualism. It is a veritable *reductio ad absurdum* of his fundamental principles.

SUMMARY OF CHAPTER VIII

From the maze of conflicting theories which followed Kant and Hegel many signalize a return to realism.

1. *Sensism, Positivism, Materialism.* They all agree in this that sense-knowledge is the only true and scientific knowledge.

2. *Natural Realism, Transfigured Realism.* The Scottish School reverted to natural realism. Hamilton, though a follower of Reid, is a relativist and phenomenalist. Spencer restricts all knowledge to phenomena, but admits the existence of an unknown and unknowable ultimate reality; our ideas are 'symbols,' giving us a 'transfigured realism.'

3. *Post-Kantian Realistic Trends.* Among the followers of Kant, who attempted to bridge the gap between noumenon and phenomenon to realism, are Jacobi, Fries, Herbart, Husserl and Meinong.

4. *Neo-Absolutism.* Schopenhauer conceived the Absolute to be the Will; E. von Hartmann, the Unconscious. The NeoHegelians, like Bradley, Green, and others, approach the Absolute through experience.

5. *Neo-Psychologism.* It applies the principles of empirical science to consciousness, seeking to harmonize idealism with science. Representative thinkers: Poincaré, Mach, Avenarius, Wundt.

6. *Personalism.* Closely allied to classic idealism, it seeks to avoid the absolutistic implications of idealism by insisting on the element of personality. Typical personalism is dualistic and theistic. Lotze and Bowne are representative.

7. *Pragmatism, Humanism.* It is a protest against idealism and a return to realism: the attitude of looking away from first things, principles, categories, supposed necessities, and of looking toward last things, fruits, consequences, facts. Truth is judged by events and consists in verification; that which works' and satisfies human needs, is true. Chief proponents are James, Schiller, Dewey. Dewey stresses instrumentalism; Bergson, intuitionism; Vaihinger, fictionalism; Fawcett, imaginism; Baldwin, pancalism; Blondel, religious pragmatism (modernism).

8. *Neo-Realism.* Neo-realists identify mind and consciousness with objects; objects, when known, are 'ideas' and as such are directly and identically present in consciousness. This is pan-objectivism and epistemological monism.

9. *Critical Realism.* This is a form of epistemological dualism; thought and thing are distinct and independent. The datum of sense-perception is the 'essence' of a thing. Essences are logical entities, the 'what' of a thing divorced from its 'that.'

10. *Emergent Evolution.* Through evolution new and unpredictable properties originate and thereby form new and higher levels of reality. These emergents have no counterpart in the lower levels. The general trend of evolution is from space-time to matter, life, mind, and deity.

11. *Objective Relativism.* All perceivable objects are relative to the perceiver, so that they owe their nature and existence to the relations in which they stand to the perceiver; and this relativity is such that phenomena are

physically objective according to the experience-set of the observer.

12. *Aristotelian-Scholastic Realism*. It is a form of natural realism and natural dualism. Though some neo-scholastics lean toward representative realism, direct perception in some form is maintained. Mind and body are an organic compound and form an epistemological unit of perception.

Chapter 9

FALLACY OF IDEALISM

THE FOREGOING REVIEW OF THE TRENDS IN MODERN PHILOSOPHY was necessarily brief. It will suffice however, to indicate the maze of contradictory theories which have arisen in this relatively short period of time. Almost every thinker has his own particular brand of theory, more or less at variance with that of his fellow philosophers. There seems to be hardly a single point on which they all agree, when they begin to expound the details of their system. On the surface, there appears to be nothing but intellectual chaos. Viewed from a broader standpoint however, by far the majority of these theories and systems will be seen to be more or less alike. They reveal a common parentage and show a common kinship. As such, then, they must possess a uniform trait, a fundamental doctrine identical in them all, which underlies all the variants and forms the root-idea from which they derive their origin and then develop into different philosophies. This uniform trait is idealism, and the root-idea is the *idealist postulate*.

It would be an impossibility to submit every form and variant of idealism to a critical evaluation. Nor is this necessary. If it can be shown that the fundamental doctrine

the root-idea, of idealism is essentially fallacious, then idealism itself as a system of thought, no matter what its individual shade and shape, will also be shown to be essentially fallacious.

THE COMMON ELEMENT IN IDEALISM

Idealism arose out of the difficulty of understanding and explaining how the human mind can transcend itself and know extra-mental reality. The ordinary man sees no difficulty in this; for him there is no problem. He sees houses; he hears sounds; he smells odors; he tastes flavors; he touches objects: these are plain, everyday facts; what more is there to say? The epistemologist acknowledges these facts, and he finds his problem precisely in these facts. Certainly we see and hear and smell and taste and touch; but what do we perceive in these psychical acts and *how* do we perceive these supposedly extra-mental things? The extra-mental objects (if there be such) cannot very well leave their location, travel through the intervening space, pierce the body, and enter the mind in their physical being; the house across the street, for instance, remains across the street and the red of the rose remains in the rose out there in the garden. And the mind assuredly does not leave the body, flit through space, and envelop the star billions of miles away in its physical being; the mind remains here and the star remains there. How then, can the mind perceive things at a distance, or how can things get into the mind? It does not seem to solve the difficulty by referring to the stimuli (light-waves, air-waves, etc.), which are supposed to

leave the objects and impinge upon the sense-organs; because then we should perceive these stimuli and not the objects from which they come. That, however, is not the case: we perceive apparently objects and certainly not stimuli.

The greatest difficulty lies in the fact of the dissimilarity which exists between mind and matter. The mind is psychical, while the objects are physical; the mind is unextended, while the objects are extended. How can the mind assimilate something so diametrically opposed to its own nature? And how can physical, extended objects impress themselves upon a mind which is altogether devoid of all extension? Can the extended become unextended, or the unextended become extended? Can the physical become psychical, or the psychical become physical? Is this not a contradiction in terms? Since the mind is psychical, it seems perfectly obvious and logical, that nothing but what is psychical can affect the mind and nothing can proceed from the mind but what is psychical. All knowledge, then, since it proceeds from the mind and takes place in the mind, must be purely mental. Physical objects are, therefore, absolutely excluded from knowledge: *the objects of knowledge are mental objects, ideas*. Consequently, even when we apparently perceive external and extended objects, what we really perceive are 'mental objects, 'ideas,' 'conscious states, 'representations,' but not physical, extra-mental things themselves. All we can perceive is our 'ideas' of things; whether anything corresponds 'out there,' extra-mentally, to these 'ideas,' is something we can never actually know. If such extra-mental objects exist, we simply

cannot know them, because they are physical entities, and the mind is restricted to the mental, the psychical, the ideal, in all its processes. As far as the mind is concerned, its objects have 'being' only in so far and so long as they are 'perceived': *esse est percipi*. Such 'being' is then not physical, but ideal; and since it proceeds from, and resides in, the mind as its 'subject,' it is subjective. All objects of our knowledge are, therefore, ideal and subjective, because they are mental products. This doctrine, that the mind in its knowing can know only its own 'ideas' or 'percepts, is *idealism*; and when this doctrine is accepted as an axiom or postulate, it is the *idealist postulate*.

This line of reasoning, formulated in many different ways, though seldom cast into strict logical form, is basic to idealism. It can be worded thus: Objects, so far as the knowing mind is concerned, exist only when perceived; but perception ('being perceived') is a conscious mind-state or 'idea'; hence, objects are only conscious mind-states or 'ideas'; consequently their existence or 'being' (*esse*) is nothing but 'being perceived' (*percipi*): *esse est percipi*. The argument originated with the antithetical dualism existing between body and mind, as postulated by Descartes.

THE FALLACY OF THE IDEALIST POSTULATE

Logic is not the strong point of modern philosophers. They disdain the strictly logical formulation of arguments and prefer the loose language of the essayist. And loose language often hides loose thinking. We can see this clearly in the argument of *Berkeley* if we cast his thoughts into

strict form. A close analysis will reveal the fallacy underlying his argument. Here are his words: "What are the aforementioned objects [houses, mountains, rivers, and, in a word, all sensible objects] but the timings we perceive by sense? and what do we perceive besides our own ideas or sensations? and is it not plainly repugnant that any of these [ideas or sensations], or any combination of them, should exist unperceived?"¹ A casual reading of this argument sounds plausible enough; in fact, it almost seems self-evident; and to many this line of reasoning has appeared so transparently and unanswerably obvious, that it has been accepted without question and become the dogma of idealism. It deserves, therefore, to be analyzed more in detail.

It will be evident that the conclusion of the idealist argument will have to be that objects cannot exist in reality except when they are perceived, because it is the contention of the idealists that the 'being' of objects is their 'being perceived.' So far as we are concerned, they cease to 'be' once they cease to 'be perceived.' Here is the syllogism:

Ideas or sensations cannot exist unperceived;
But sensible objects (houses, etc.) are ideas or
sensations;
Ergo, sensible objects (houses, etc.) cannot exist un-
perceived.

The fallacy lies in the minor premise: "Sensible objects (houses, etc.) ideas or sensations." The term 'sensible objects' can be taken in two meanings: objects can be called

'sensible' in the meaning of 'actually sense-perceived' and in the meaning of 'potentially sense-perceived.' In the first meaning they are perceived in the act of perception; and in the second meaning they can be perceived. In the first case we have objects which are 'within' the act of perception, and in the second case we have objects which are 'outside the act of perception but are capable of being perceived. In either case such objects would be called 'sensible.' The difference lies in the fact that in the first case these 'sensible' objects are considered as 'perceived, while in the second case they are merely 'perceive-able.' Berkeley confuses the two meanings: he identifies the 'perception of objects with the objects of perception. His argument merely proves that 'sensible' objects *when perceived* are ideas or sensations'; but it says nothing whatever about such *objects when not perceived*. All that his argument can prove is that 'objects are perceived when we perceive them'; and that, though true, is plainly a redundancy and a juggling of words but no proof that things 'cannot exist unperceived.'

If he contends that the argument also holds in the second meaning, so that there are no sensible objects outside the act of perception which are unperceived but perceive-*able*, he begs the whole question by presupposing in his premise what is supposed to be the burden of the conclusion. Such a contention is an unwarranted assumption. "Sensible objects are ideas and sensations" when perceived; but that is no proof that they cannot be objects in and for themselves without being perceived. What idealists prove is merely that 'sensible objects cannot be *perceived as existing* without being perceived as ideas

or sensations'; but this in no way proves that 'sensible objects *cannot exist* without being perceived as existing.' Because objects, when perceived, have now a 'subjective existence,' it does not follow that such objects have a 'subjective existence' only. Things could possibly have an 'objective existence' for themselves and then obtain an added 'subjective existence' in the subject when perceived by the subject. In order to establish their case, idealists would have to disprove this possibility; but this their argument fails to do.

The fallacy of the idealist argument will, perhaps, be more clear if we cast it into the form of a hypothetical syllogism. It could be made to read in the following manner:

If something has a purely subjective existence, it has
a mental existence;
But perceived objects have a mental existence;
Ergo, perceived objects have a purely subjective
existence.

The major premise contains a true statement: anything that has a purely subjective existence is mind-dependent, because it is produced by the mind; it has, therefore, a mental existence. The minor premise is also true: when objects are perceived, they are perceived by the mind and as such exist cognitively in the mind; they have, then, a mental existence. But the conclusion does not follow logically from these premises. It is the *fallacy of false consequent*. The minor premise posits the consequent instead of the antecedent, and that is not logically

permissible. If we wish to avoid this inconsistency and make the minor premise posit the antecedent, the syllogism will read:

If something has a purely subjective existence, it has
a mental existence;

But perceived objects have a purely subjective
existence;

Ergo, perceived objects have a mental existence.

But now the argument does not prove enough. It merely proves that perceived objects have 'a mental existence,' and that is something which the realist admits; the idealist, however, desires to prove that all perceived objects have *nothing but* 'a purely subjective existence,' since it is his contention that the '*esse*' of all perceived objects is their '*percipi*.' The argument does not reach that far. Besides, in the syllogism, as now given, the minor premise states that 'perceived objects have a purely subjective existence.' This statement begs the question in dispute, because here the '*esse est percipi*' is already assumed as true, while the truth of this fact is supposed to be found only in the conclusion.

There is only one more way in which this argument can be formulated so as to be logically correct and consistent. It could be made to read as follows:

If something has a mental existence, it has a purely subjective existence;
But perceived objects have a mental existence
Ergo, perceived objects have a purely subjective existence.

This syllogism is consistent, but the conclusion is not true. The major premise, as it stands is again a begging of the whole question. The fact in question is precisely that which is assumed in the major premise: Is it a fact that, if something has a mental existence, it has a purely subjective existence? This is the very point which the idealist intends to prove by the argument; hence to assume its truth in the premises is an illegitimate procedure.

It is thus seen that the fundamental position of the idealist is untenable, because illogical. He cannot prove that the objects we perceive have only a subjective existence in the mind; for all he knows, they may have a mind independent, objective existence in nature also. And if objects can exist both in nature and in the mind (and no valid reason has been adduced to the contrary) then the fundamental idealist postulate is invalid. D. C. Macintosh has summarized the essential fallacy of idealism in these concise words:

“The fallacy may appear as one of equivocation — the common fallacy of ‘four terms’ — as in the following syllogism: What is subjective (*dependent* on self for existence) is not externally real, but mere idea; all objects of which we are aware are subjective (*related* to a self which is conscious of them); therefore, all objects of which

we are aware are not externally real, but mere ideas. Or, if the equivocation he avoided, the fallacy will remain as that of an 'undistributed middle term,' as in this syllogism: The unreal objectively is subjective (related to a subject); Similarly all of which one is conscious is subjective (related to a subject); therefore, all of which one is conscious is unreal objectively (mere ideas). Or, more simply, psychological idealism may be said to rest upon a fallacious conversion. From the obvious truth that all elements which depend on consciousness for their existence, such as pains, feelings, desires, etc., are in the subjective relation, i.e., are objects for a subject it is inferred, by the fallacious process of simple conversion, that all that is in the subjective relation, all that is object for a subject, is dependent on consciousness and this relation to consciousness for its own existence."²

THE EGO-CENTRIC PREDICAMENT

Every form of idealism, whether dualistic or monistic, rests upon the *primacy of consciousness*. Things simply cannot be known, perceived, experienced, except by a conscious mind. Consciousness is thus for them the universal condition of all knowledge and also of being. Consciousness *constitutes* its objects; and if this consciousness maintains its own individuality in the human mind, we have dualistic idealism and if it is merged in a universal Ego, we have monistic idealism. In either case the 'object known' is identified with the 'subject knowing.' We have seen how Berkeley argues for the oneness of the material reality with

the perceiving mind. Bradley argues in a similar fashion for the oneness of all reality with sense-experience. Immaterialism, phenomenalism, absolutism, and every shade of idealism, ultimately base their doctrine on the fact that reality is somehow enclosed within the realm of consciousness, for the simple reason that we cannot perceive objects as existing apart from consciousness perception. This ultimate fact, which is the heart of idealism, thus rests on what has been so aptly styled 'the ego-centric predicament.' Here is Perry's exposition of the idealist fallacy as based on the egocentric predicament:

"No thinker to whom one may appeal is able to mention a thing that is not an idea, for the obvious and simple reason that in mentioning it he makes it an idea. No one can report on the nature of things without being on hand himself. It follows that whatever thing he reports does as a matter of fact stand in relation to him, as an idea, object of knowledge, or experience. . .

"This predicament arises from the attempt to discover whether the cognitive relationship is indispensable to the things which enter into it. In order to discover if possible exactly how a thing is modified by the cognitive relationship, I look for things *out* of this relationship, in order that I may compare them with instances of things *in* this relationship. But I can find no such instances, because 'finding' is a variety of the very relationship that I am trying to eliminate. Hence I cannot make the comparison, nor get an answer to my original question by this means. But I cannot conclude that there are no such instances; indeed, I

now know that *I should not be able to discover them if there were.*"

"Just in so far as I do actually succeed in eliminating every cognitive relationship, I am unable to observe the result. Thus if I close my eyes, I cannot see what happens to the object; if I stop thinking, I cannot think what happens to it; and so with every mode of knowledge. In thus eliminating all knowledge, I do not experimentally eliminate the thing known, but only *the possibility of knowing whether that thing is eliminated or not.*"

"This, then, is 'the ego-centric predicament.' But what does it prove, and how does it serve the purpose of idealism? It should be evident that it proves nothing at all. It is simply a peculiar methodological difficulty. It does, it is true, contain the proposition that *every mentioned thing is an idea*. But this is virtually a redundant proposition to the effect that every mentioned thing is mentioned — to the effect that every idea, object of knowledge, or experience, is an idea; object of knowledge, or experience. And a redundant proposition is no proposition at all. The assertion that an idea is an idea conveys no knowledge even about ideas. But what the idealist requires is a proposition to the effect that everything is an idea or that only ideas exist. And to derive this proposition directly from the redundancy just formulated, is simply to take advantage of the confusion of mind by which a redundancy is commonly attended."

"It may be argued, however, that the ego centric predicament is equivalent to an inductive proof of the proposition that all things are ideas. Every observed case of a thing is a case of a thing observed. Neglecting the

redundancy, which is sufficient of itself to vitiate the assertion, we remark that the induction proceeds entirely by Mill's 'method of agreement,' which is invalid unless supported by 'the method of difference, that is, the observation of negative cases. But the egocentric predicament itself prevents the observation of negative cases. It is impossible to observe cases of unobserved things, even if there be any. In other words, there is a reason connected with the conditions of observation why only agreements should be observed. But where this is the case the method of an agreement is worthless; and the use of it is a fallacy."³

Perry's criticism of the idealist argument from the egocentric predicament is eminently justified. The argument is essentially fallacious. The only way in which we can become acquainted with things, is to perceive them or have ideas of them; therefore, *if and when and while* we know them, they must be 'percepts' or 'ideas' in our consciousness. The very nature of our knowing demands this. But things could possibly have existence without being perceived and thus be mind-independent in their being; all that the egocentric predicament can prove is that things *cannot be perceived without being perceived*, which truth, of course, amounts to a mere tautology.

If we now turn to Bradley's idealist argument, it will be evident that it is nothing but a sample of specious reasoning from the ego-centric predicament. He says: "Find any piece of existence, take up anything that anyone could possibly call a fact, or could in any sense assert to have being, and then judge if it does not consist in sentient experience.

Anything in no sense felt or perceived becomes to me quite unmeaning."⁴ Certainly, things 'in no sense felt or perceived' must be 'unmeaning' *to the perceiver or knower*; for how could they acquire a meaning for him, if he did not 'feel' or 'perceive' them? That would imply 'knowing' them without someone knowing them, and 'perceiving' them without someone perceiving them. The very fact of cognition always involves the perceiver or knower just as necessarily as the object itself that is to be known; because an object, to be known, must be known by someone. Wherefore, Bradley's argument only proves that objects cannot exist for a perceiver and knower without sentient experience; but it says nothing whatever about what objects can or cannot be for themselves outside the knowledge relation, and Bradley's conclusion that 'experience is the same as reality' is thus seen to be entirely unwarranted. The ultimate nature of reality is still an open question.

The whole attitude of the idealist, of whatever type he may be, rests upon a confusion of ideas. From the fact that a being, in order to be known, must be perceived within the consciousness of the perceiver in a mental act, he concludes that the 'reality itself' of the being, and not merely its 'perception,' is mental.

Reality would thus be *immanent* in the knower. The confusion is based on the identification of the 'reality' and the 'perception' of the object known. It is unquestionably true that the 'perception' of an object is mind dependent and immanent. To assert that an object, *when known* can remain unperceived is a contradiction; and it would also be a contradiction to assert that an unperceived object, when

unperceived, can be known. But it is no contradiction to assume that an object, which has a reality of its own, can remain unperceived by a human mind, either temporarily or forever, either in part or in whole. We would simply not know of its existence until such time when it enters our experience. To deny that such an object can exist as an 'unperceived reality' means to confuse the *reality* of this object with the *perception* of its reality. This is precisely what idealists do, but it is an illogical and dogmatic procedure and therefore fallacious.

The foregoing criticism shows that idealism arises out of the ego-centric predicament and that its arguments involve a faulty logic. This, of course, does not prove that extra-mental reality actually exists; it merely shows that idealism has not disproved the existence of extra-mental objects. The question of the existence of such objects must be solved, not by any *a priori*, but by an *a posteriori* method. Facts alone, together with their proper interpretation, must settle the issue; that is the only scientific and philosophic procedure which can lead us with safety to a definite conclusion.

SUMMARY OF CHAPTER IX

1. Most modern theories of knowledge are a form of *idealism*. The fundamental position of idealism is fallacious.

1. The element common to all forms of idealism is the tenet that reality lies within the consciousness of the perceiver and the mind cannot transcend its own conscious states. It arrives at this conclusion through the difficulty of understanding how the mind can perceive objects at a distance and how a psychical mind can conform itself to a physical object. Hence, there has arisen the idealist postulate that the mind in its knowing can know only its own 'percepts' or 'ideas.' The argument can be formulated as follows: Objects, so far as the knowing mind is concerned, exist only when perceived; but perception ('being perceived') is a conscious mind-state or 'idea'; hence, objects are only conscious mind-states or 'ideas'; consequently their existence or 'being' (*esse*) is nothing but 'being perceived' (*percipi*): *esse est percipi*.

2. The Idealist Postulate of idealism is *fallacious*. Berkeley's argument that *esse est percipi* is grounded on faulty logic. His term 'sensible object' is ambiguous, because he does not distinguish between the 'sensible' as perceived and as perceivable. He merely proves that 'sensible objects', when perceived, are 'ideas or sensations', so that his proof really amounts to the redundant proposition that 'perceived objects must be perceived.' The fallacy of idealism thus consists in confusing the statement that 'sensible objects cannot be perceived as existing

without being perceived' with the statement that 'sensible objects cannot exist without being perceived as existing'. To assume that the latter statement is true, is a *petitio principii*. All arguments which tend to prove that all reality must be identified with 'ideas' involve either a 'four-term' syllogism, or an 'undistributed middle,' or a fallacious 'conversion.'

3. The ego-centric predicament, or the difficulty to discover any objects outside the cognitive relationship existing between object and subject, is responsible for the fallacy of idealism. Dualistic and monistic idealism rests upon the primacy of consciousness. Since consciousness is the universal condition of knowledge, it is also assumed that consciousness constitutes the being of all objects of knowledge. Due to the ego-centric predicament, every mentioned thing is an 'idea', and from this idealists conclude that everything is an 'idea' and that only ideas exist. But this reasoning is fallacious, because it merely proves that objects, if and when and while known, must be 'percepts' or 'ideas'; in other words, 'things cannot be perceived without being perceived', which is a redundancy and a platitude. The argument, however, does not prove that objects may not *exist in themselves*, as mind-independent things; without being perceived. The whole attitude of the idealists is based on the confusion of identifying the *reality* of an object with the *perception of this reality*; they fail to distinguish between the 'knowledge of objects' and the 'objects of knowledge.'

The foundation of idealism thus rests on faulty logic and on the ego-centric predicament. The existence of extra-

mental things is a question which can be settled only by a close analysis of the facts and by the proper interpretation the facts; not the *a priori*, but the *a posteriori* method can solve the problem.

Chapter 10

EXTRA-MENTAL AND EXTRA-EGO REALITY

FROM THE WELTER OF CONFLICTING SYSTEMS AND THEORIES OF knowledge which have come into vogue during the last three centuries, it is possible to draw but one conclusion: there must be something radically wrong with the starting point and the method used in the attempt to solve the problem of knowledge. When the results are so disastrous, the principle must be faulty. The only logical thing to do, then, is to disregard these systems and begin the solution of the problem from a common-sense standpoint: scrutinize the facts, note their implications, interpret their meaning, and draw the implied conclusions.

Three main factors enter into the problem: the human *mind*, the human *body*, and the external physical *world*. The body, if it exists, is an extra-mental reality, distinct from the mind; but it belongs to the human Ego as an integral part, together with the mind, and as such it would be extra-mental but intra-Ego. The physical world, on the other hand, if it exists, would be extra-mental and also completely external to the perceiving subject; it would be extra-Ego and non-Ego. The best procedure will be, therefore, to see whether we can vindicate the existence and perception of

the extended, extra-mental human body, and then proceed to investigate the existence and perception of the extended, external world: because the world cannot come into contact with the mind except through the body. If the existence and perception of the body, as distinct from the mind, cannot be vindicated, then there is no possibility whatever of establishing the existence and perception of the external world at large.

THE DATA CONCERNING EXTRA-MENTAL REALITY

Besides my mind, I perceive within my being a reality which possesses *extensity*, and this reality I call my 'body.' There is a very definite *spatial configuration* to my body. By passing my hand over the body, I obtain a clear impression and touch-perception of its relative size and contour. I know, for instance, that my body occupies a very limited area from head to foot which, measured by a standard rule, will be, perhaps, more than five feet in height and less than six. I know, too, that different members comprise the complex of the body, and that these members occupy separate and distinct *positions*, both in relation to each other and to the body as a whole. Feet and head form the extremities, while the limbs and the torso have intermediate locations.

Touch, especially the experience of double-contact, reveals *voluminousness* in my body. In moving my hands over the body, I obtain an immediate perception of 'up and down,' 'right and left,' 'before and behind.' I thus perceive that my 'body possesses the three dimensions of length, breadth, and depth. The intra-muscular sense reveals to me

the fact that the different parts of my body change position in space: I sit, I stand, I lie down, I stretch, I bend backward, I incline forward. I also perceive that the entire body moves at times: I walk, I run, I swim, I rise, I climb. *Weight* is revealed to me in the difference experienced in ascending and descending a sharp incline or in being lifted into the air and then dropped to the ground. And *solidity* is manifested to me in the fact that one part of the body cannot penetrate the other.

My experiences also make me aware of various *sense-organs* and their *distribution* and *localization* within the confines of my body. I have eyes to see, ears to hear, a palate to taste, a nose to smell, and touch pervades the entire body. Each organ, I note with intuitive consciousness, has its own *specific type of object for perception*: colors, flavors, sounds, odors, heat and cold, pleasure and pain, hardness and softness, smoothness and roughness, freshness and fatigue. During active sensation I experience, by means of the intra-muscular sense, the precise *place* on and within the body where the sensation is localized; in this manner I experience not only the actual perception as such (for instance, the perception of color, sound, etc.), but also the organic *activity* accompanying this perception, showing me that the perception is mine and belongs to a definite portion of *my body*.

In this manner I have a clear picture of my body in its parts and as a whole. Furthermore, and this is important, in this concrete picture I concretely perceive through immediate awareness that my body is a reality distinct from the thinking mind; it is an *extra-mental reality*. At the same

time, however, I am also concretely aware that my body is an integral factor, together with the mind, in the *process of perception*. If I close my eyes, I cannot see; if I open them, I see again. If I touch a burning object, I experience heat; if I withdraw my hand, the sensation ceases. If I push against a wall, I feel resistance; if I step away, the feeling of resistance ends. And since the sensation becomes perception only when the mind adverts to it and becomes aware of it, I notice that both body and mind are necessary for perception, although I clearly realize that both are not the same thing. *But both are felt to belong to my Ego*. It is my body and my mind; I think and am conscious, and I weigh so-and-so-much and move about from place to place. Whatever affects my body I am conscious of as affecting *me*, and whatever takes place in my mind I am aware of as taking place in me. My Ego is thus perceived to be something that possesses both body and mind, forming a unitary combination of the two which, notwithstanding their distinct differences, makes them act together in perception.

These, then, are in brief the data of consciousness regarding my 'body.' These data cannot be denied; for any person, observing himself in the manner indicated above, will readily verify them through his own experience. The facts must be accepted; it is in the interpretation of them that various theories arise.

THE EXISTENCE OF EXTRA-MENTAL REALITY

In placing an interpretation upon the aforementioned data, it must be borne in mind that no *a priori* presuppositions or

theories can be allowed to dictate the explanation. The facts must speak for themselves, and mere difficulties do not constitute impossibilities. The facts must assuredly be accounted for, and that theory alone should be accepted as true which gives the most natural explanation of the data in their entirety. Now, the most natural and most general explanation is the one which claims that my perceptions *reveal my body as an existent reality*.

This view is in agreement with the spontaneous conviction of men in all ages. Even the educated and intelligent, notwithstanding their knowledge of physics and psychology, accept the reality of their own body as an indubitable fact, because this view alone harmonizes with *everyday practical life*. Our entire mode of living is devoid of sense and reason, if the reality of our own body be considered merely as an 'internal state,' 'idea,' 'image,' 'representation,' or 'percept' of the mind. When we give food and drink to the body, when we labor unto fatigue and exhaustion, when we are sick and in suffering, when we break an arm or undergo an operation, when we experience physical comfort and pleasure, when we grow from childhood into maturity and decline into old age — these actualities of life are meaningless except under the supposition that our body is a *physical reality* just as we perceive it to be in consciousness. Idealism, with its reduction of all knowledge to terms of mental 'percepts' or 'ideas,' may do in books and in classrooms, but will serve little purpose in the stark necessities of life which confront man in his bodily being day after day. Idealism puts no bread into the mouth of the starving and eases no pain in

the sick. Only an idealist philosopher could be satisfied with the theory that the reality behind his bodily 'appearances' and 'phenomena' is some unknown and unknowable, unperceived and unperceivable x; our body is far too real and personal for us to rest content with such vaporous hypothetical existences. And even the most inveterate idealist is only an idealist *in theory*; when he goes about his daily occupations and supplies the daily needs of his 'phenomenal' body, he acts and behaves like the simplest and most plebeian realist. But a theory that cannot be *lived*, that must be contradicted by every un-philosophical act of daily life, must be essentially wrong.

This view also agrees with *science*. The departments of anatomy, physiology, biology, physics, genetics, medicine, and psycho-physics, when not influenced by the purely theoretical considerations of idealistic thinking, are frankly *realistic*: they accept the human body as given and as perceived, and their treatment of it shows plainly that they are convinced of its reality and existence. Here again, some scientists may be idealists in theory, but in every practical issue they are realists. This, of course, does not prove that realism is necessarily true in itself; it does show, however, that human reason can accept an idealistic interpretation of the human body only by doing great violence to its natural judgment.

After this indirect argument, we must consider the *direct evidence of consciousness*. Consciousness, as was shown before, must be essentially free from error in all matters of which it has immediate intuition. To doubt or deny this is equivalent to the suicide of reason, because then all

knowledge must be adjudged illusory. But the evidence of consciousness is transparently clear in testifying to the reality and existence of our body. We can discover no difference between the intuition which consciousness has of mental states and that which it has of the reality and existence of the body. There is indeed a difference in the *object* of awareness, but there is no essential difference in the *nature of the act* of awareness itself. Now, if this act of awareness is perceptive of the reality and existence of internal states, why should it not be equally perceptive of the reality and existence of the human body with which it is so obviously connected? The testimony of consciousness is equally clear and intuitive in both cases. To affirm the validity of its perception in the one case and to deny it in the other, amounts to a practical destruction of its character as a reliable witness in both. We could no longer trust its testimony; certain knowledge would be impossible, and skepticism would inevitably follow. Hence, the testimony of our consciousness concerning the reality and existence of our body as perceived by us must be accepted.

THE PERCEPTION OF EXTRA-MENTAL REALITY

The entire difficulty of the idealists arises from the view, prevalent since Descartes, that mind and body are so antithetical and foreign to each other, that there can be no real communication between the two. The mind is conceived as a purely unextended entity which is the total subject of knowledge. This view of the 'subject of knowledge' is arbitrary and false; it is an unwarranted

assumption, contradicted by the very data of consciousness. *My Ego is the real subject of my knowledge*: that is the verdict of my consciousness. The mind is a mere instrument of my Ego, and this is clearly perceived by introspection: I think, I imagine, I remember, I judge, I reason. It is the Ego, then, and not the mind itself, which is the ultimate subject of intellectual knowledge. And the same is true of sensory knowledge: I feel, I see, I hear, I have pain in my hand, I have a fever. Thus it is seen that the Ego is the real subject of both intellectual and sensory knowledge, that is, of all knowledge. Now, if we analyze our sensory knowledge, we must come to the conclusion that it involves 'extension' in the very *act of perception*. I perceive, for instance, 'colored surface'; but how could I perceive a 'surface' which is extended, if my act of perception were totally unextended? I feel the 'whole length of my arm'; how can I feel or perceive such a thing, if my feeling and perception were wholly mental? I experience a pain 'down my left side'; again, how is such an experience possible, if there be no extension in the act of perception? We could multiply such instances by the thousands. They are evident data of our consciousness. But these facts are unintelligible, if we maintain that sense-perception takes place in an unextended subject.

Sense-perception is a vital act, certainly; but it is also an 'extended' act. The *subject* of sense-perception must, therefore, also be a *vital and extended reality*. And since the Ego is the real subject of sense-knowledge, it must be a reality which is both vital (perceptive) and extended. Only a body, however, is extended. Consequently, an extended body must form an integral part of the being of our Ego, in order

to account for the *psycho-physical* character of our sense-perception as a vital yet extended act. We are thus forced to conclude that our Ego does not consist solely of our unextended mind, but is a *compound of mind and body*, united in such a way that our Ego is a unified living organism consisting of both. Neither the mind alone nor the body alone can explain sensation and perception; both are required for an adequate explanation. And both must be fused together so intimately in their being, that they form a single principle of perceptive action.

Since our body is an integral part of our Ego and is thus *partly identical* with it, our Ego must be capable of perceiving its body just as well as it is capable of perceiving its own mind with its internal states: both belong as constituents to and in our Ego. There is, then, no intrinsic impossibility for our Ego to perceive its own body; on the contrary, the Ego should be able to perceive that which is a component part of itself as a factor in sense-perception.

The above analysis of the data of our consciousness concerning the reality and perception of our own body shows how arbitrary and fundamentally wrong Descartes was in his treatment of the relation existing between mind and body in the human being. In his eagerness as a mathematician to deduce all knowledge from a single principle he disdained to submit the data of our consciousness to a close scrutiny. Instead, he attempted to give an *a priori* definition of mind and body and built his entire theory of knowledge upon this foundation. The facts of experience certainly do not bear out his antithesis. We are conscious beyond doubt that we are *one single being*,

not two, and this presupposes that the mind-body combination in our person is a unitary principle of action. It takes more than a definition and a statement to sever the union between them. Simply because 'thought' is an obvious characteristic of mind, Descartes judged it to be the *exclusive* characteristic of mind and proceeded to define 'mind' as 'thought'; and for the same reason he defined 'matter' (body) as 'extension.' But this is the fallacy of *definition by initial predication*, and on this fallacy the whole system of idealism has been reared.

THE DATA CONCERNING THE NON-EGO WORLD

Unquestionably, much of our knowledge of the external world, which we ordinarily consider directly given in sense-perception, is acquired through a very complicated process of perception, intellectual abstraction, and mental inference. We are not brutes, but intellectual beings; we not only perceive, but think. Consequently, it is not always easy to distinguish what is due to direct sense-perception from that which is the result of our interpreting judgment. Nevertheless, the primary facts are plain and simple. The very data which reveal to us our body as real and intra-Ego, reveal to us *concretely* at the same time and in the same way that bodies exist which are extra-subjective and extra-Ego: they possess the feature of *externality* and *otherness*.

The sense of *touch* is fundamental in this respect. When I move my hand over parts of my body, I perceive that my hand is distinct from these parts. At the same time, however, I also perceive that the parts touched are not

foreign to my being but belong to it as well as my hand does: they are all parts and members of the same organic, structural whole. But when my hand touches a book, a desk, an apple, a building, a tree, a human body (other than my own), it is immediately clear to me that these things *do not belong to my being*; they are 'other,' extra-Ego, external, something totally different from my self. All the objects which I contact while moving through space are thus perceived to possess this characteristic of 'otherness.' I can move my own bodily members from place to place, but I observe a definite *resistance* exerted against my body by many things. I cannot walk through them, neither can I surmount them nor push them aside; they are unyielding objects which block my path, so that I am obliged to walk around them. I thus experience objects with triple dimensions, with solidity, with weight, with impenetrability, with permanence and stability.

Besides this passive resistance to my body, I also experience the *active influence* of other bodies upon my own. Fire burns it, water wets it, a stone bruises it, dirt soils it, a heavy object breaks and crushes it. These things are not perceived by me to belong to my organism as a part of my being and self; on the contrary, just because my organism is clearly intuited as consisting of definite members occupying definite limits of space, I *concretely* perceive at the same time that these 'other' objects are external to me, having a real existence for themselves independent of my own.

The sense of *sight* also reveals 'externality' and 'otherness,' when taken in conjunction with the sense of

touch and assisted by conscious experience. I soon learn to interpret the visual picture according to the more immediate perceptions of touch. My right hand touches my left arm; and my visual image coincides so completely with my tactual experience, that I thereby discover that the 'thing touching' is my right hand, while the 'thing touched' is my left arm. A number of such experiments helps me to 'identify' visually the various parts of my body with accuracy and security. Once this identification is an established fact, my sight unerringly distinguishes between my own body and objects *external* to my body. A blind man clearly perceives the 'otherness' and 'externality' of objects outside his bodily frame, but a person with sight possesses the added perception of the more far-reaching and more clearly defined visual image. When touch and sight are united in perception, the result provides an overwhelming amount of data which reveal an evidently real and existing material world of 'external' objects. I thus learn that my body occupies a relatively small amount of space, while the world is a tremendously large place filled with innumerable objects, large and small, at rest and in motion, permanent and changing, endowed with characteristics which are partly the same and partly very different from those of my own body.

THE EXISTENCE OF THE NON-EGO WORLD

In establishing the reality and existence of this external, non-Ego world so vividly presented in our perception, the procedure is practically the same as in proving the reality

and existence of our extra- mental body. If our own extended body must be admitted as real, there can be hardly less reason to admit the extra-Ego world as real; for, after all, our own body is also a *part of the world at large*, possessing the same general characteristics and features as those possessed by 'external' bodies.

Whatever *theoretical* difficulties idealists may find in the perception of an external world by an unextended mind, it is obvious that their theory does not harmonize with the exigencies of practical life as lived by everybody, including these theorists themselves. The things of this workaday world are simply too real to be argued out of existence in this fashion. If our body is real, the world is real. No mother can ever consider her child and her pains to be the same, mere 'felt-experiences.' No soldier in the ghastly turmoil of war, with his leg ripped to shreds by a shell, can be made to believe that the bullets and shells he faced and the men and guns he fought were only 'conscious states.' When the farmer plows his field, and the laborer digs his ditch, and the ironworker rigs his beams, and the engineer runs his train — in short, when man lives his routine life in his daily occupations, he cannot but be a thoroughgoing realist concerning the world of material objects around him. All humanity cannot be wrong, and a few idealist philosophers right, in their view regarding the reality and existence of the external, physical world. If idealist theories cannot agree with this 'realism of the savage,' as demanded by practical living, then so much the worse for these theories: there must be something radically wrong with them.

Plain realism is in accord with the findings of the *sciences*. Astronomy, physics, geology, anthropology, zoology, botany, chemistry, bacteriology, therapeutics — in fact, all the natural sciences have sense and meaning only on the assumption that nature is a real world of existing, extended, material objects. The laws of nature which scientists formulate have application, not to mental states and subjective phenomena, but to the physical objects in a mind-independent existence. Their observations and experiments in no way impugn the realistic conception of the universe; if anything, they confirm it, even when age-old beliefs are proved to be naive and erroneous.

The reason why our mind is naturally convinced of the reality of the external world as we perceive it to be, lies in the fact that we are intuitively aware that we do not produce our impressions and perceptions of the external objects: we are passive, in the sense that our consciousness testifies that the impressions and perceptions are *produced in us from outside*. We cannot produce them at will, nor can we change them at our convenience. But if the objects, as we perceive them, were only internal modifications of our consciousness, without a reality of their own, why this *persistence*, this *regularity*, this *permanent order*, this *compulsion*? Many of our perceptions are painful, unpleasant, nauseous, embarrassing, nerve-racking; though we fain would rid ourselves of them, we cannot. The reason is plain: these impressions are made by objects which are real and over which we have no control. We are *forced* to perceive them, if our senses are within the sphere of their influence.

THE REALITY OF OTHER MINDS

There is one thing in which idealists are egregiously *inconsistent*: they all admit, tacitly or explicitly, the existence of *other minds*. And how could they deny the existence of 'other minds,' when they appeal to them, reason with them, argue with them, quote them, and wrangle with them, all in an effort to convince them of the truth of idealism? But how do they know of the existence and thoughts of these 'other minds'? Our experience is witness to the fact that we have direct and immediate knowledge of no other mind but our own. Our knowledge, then, of 'other minds' can only be indirect and mediate. Then how? Through the medium of *language and speech*. Language may be expressed in spoken or written words, or by means of signs; but language in some form is necessary.

Idealists agree that extra-Ego reality either does not exist at all or, if it does, it is an unknown and unknowable quantity, because the mind of man is restricted in its knowledge to its own subjective conscious states. Were this the case, our mind could not know anything about 'other minds,' for the simple reason that they are not only extra-mental but *extra-Ego* with regard to ourselves. The fact of language, however, proves conclusively that 'other minds' are not the unknown and unknowable beings which the idealists would have us believe.

That this 'other mind' is an existent entity distinct from myself is clear from the fact that the *ideas* which I thus receive in the course of this thought-communication from the 'other mind' are often entirely *new* to me and are given

to me 'from without.' I am aware beyond the possibility of doubt that these ideas are not my own, are not the product of my own thinking. In many instances these ideas are so foreign to my way of thinking and so antagonistic to my own ideas that a conflict arises between the two sets of ideas and a controversy or argument ensues between 'my mind' and the 'other mind.' How could this happen, if 'my mind' and the 'other mind' were identical in being? Hence, the fact of language and speech proves conclusively that both 'my mind' and 'other minds' exist and that they are distinct and non-identical.

If my knowledge cannot go beyond my own conscious states, if I cannot transcend the boundary of my own knowing mind, and if all extra-Ego reality is unknown and unknowable to me, so that I cannot refer these 'extraneous' ideas to 'other minds,' then I myself must be the *originator* of all these ideas. Consider the consequences of such a theory. Whenever I read a book or listen to a lecture, the contents of the book or lecture enters my consciousness. And thus all the philosophies of the world, from Thales and Socrates and Plato and Aristotle to St. Thomas Aquinas and Descartes and Kant and Hegel and James, would perforce be the product of my own mind and its thinking! The idealist postulate demands this conclusion. This, however, is ridiculous on the face of it. No one in his sane mind would seriously assert that he alone is the author of all these different, contradictory systems of thought. If they are the result of my own thinking, why the differences and contradictions between them? And why the *difficulty in understanding some of these systems*, if I am their author?

Can anyone seriously doubt that these philosophies originate in 'other minds' and that I merely assimilate their ideas from them?

The whole argumentation can be formulated in the following dilemma. The knowledge which we naturally and spontaneously ascribe to 'other minds' either originates from them or from our mind. If the former, realism is established, because we possess a true and valid knowledge of extra-mental and extra-Ego reality. If the latter, then we cannot explain why we are not conscious of the process, why so much of this knowledge is foreign to our consciousness, why so many of these ideas and systems are contradictory to our own, and why we are compelled to 'learn' the different languages. In the former case, idealism is refuted and realism proved; in the latter case, there is a contradiction and an illusion in our mental equipment, and universal skepticism must follow. All the evidence points to the former of the two alternatives as being true.

THE PERCEPTION OF THE NON-EGO WORLD

Though our conviction in the reality and existence of the external, physical world is thus established as a fact, we still have to face the question: How can our Ego perceive something which is completely non-Ego? What is the *epistemological bridge* between the unextended mind and the extended, external world? The difficulty seems more formidable than it actually is. Once the reality of our own body is proved and admitted, the difficulty vanishes to a great extent. Our body is the 'epistemological bridge'

between our mind and the world. Our mind does not contact the physical universe directly, but through and in our body.

It is not necessary to prove that we can perceive *all* reality of the material world. If we can show that physical, external reality can be contacted and perceived *in some phase of its being*, it suffices to prove that external reality exists outside our Ego and can be perceived. Then realism is rationally justified. And this can be shown to be a fact.

Our body is an extended being, occupying space and place in three dimensions. United with the mind into a single organic principle of perceptive action, it forms a sense-conscious being. Our Ego thus feels itself to be a living, sense-conscious, *extended, corporeal substance*; this has been shown previously. As such, then, we should be capable of perceiving extended bodies, whether it be our own body or 'other bodies.' If we can perceive our body as *our own*, then any body, different from our own and in contact with it, should be perceived as *different*, and as 'other.' Such actually is the case.

I walk along the street, and I feel my body moving; my intra-muscular sense tells me that I am taking steps and that each stride covers a certain distance. If I come face to face with a wall or building, my progress is stopped; I find a barrier which effectively hinders me from continuing in motion. No matter how strenuously I push against this barrier, I cannot push it over and proceed on my way. I perceive here the same impenetrability and resistance that I experience in my own body, when I stop the progress of a moving object, like a rolling ball, with my hand or foot.

Consequently, just as I know that my body is real in resisting the ball, I know that the resisting wall or building is as real as my body; the situation, though reversed, is actually the same in both instances. When I walk alongside a building, holding my hand against it as I walk, I perceive that the building is stationary, while I am moving; but when I stand still beside a train, and feel the train passing along under my outstretched hand, I know that I am stationary and the train is moving. I thus perceive that the building and train are similar to my own body and must be just as real, but are extra-Ego and 'other.' Thus my body becomes a standard of measurement with which I can gauge the size and *distances* of things in relation to me. The reason 'why' and 'how' I can perceive them lies in their *objective commensurate-ness and corporality*, which is like that of my own body.

It is, then, through *direct contact* with my body and through the sense of touch that I can become immediately and intuitively aware of 'other' bodies in their reality and existence. I perceive my own body as 'identical with self,' while I feel these others as 'non-identical with self.' The perception and the felt- experience is the same in both cases. If my body is perceived to be real, the 'other' bodies must also be real; the former guarantees the latter. In this fashion my body acts as the 'epistemological bridge' between the mind and the world: though an extra-mental thing, my body is organically united with the mind and is related psychically to it; as an extended thing, it is of the same nature as the extended objects in the material world and is related to them. This unique position of the body as

an extra-mental, extended being within the *unity of the Ego* enables it to bring the extra-mental, extended objects of the external world into cognitive union with the mind, so that mind and world meet each other in the human body: *there*, on this epistemological bridge, is their mutual point of contact. The 'extended' but 'vitalized' body, being a psychophysical substance, is the natural link between the world of mind and the world of matter, making a perception of the latter within the former both a possibility and a fact.

Considering the facts as manifested in the data of our consciousness, we are compelled to conclude that realism, and not idealism, correctly interprets sense-perception with regard to our body and the non-Ego world. The spontaneous conviction and the common-sense view of humanity is seen to be vindicated as substantially valid and true. We have now obtained two truths of tremendous epistemological value: *'The reality and existence of our own body as an extra-mental object and of the external world as an extra-Ego object is a fact; and our body and the universe can be perceived by us as they are in themselves.'* We now have a reflex, philosophical certitude regarding them: idealism cannot explain the fact, while realism does.

SUMMARY OF CHAPTER X

In order to discover whether extra-mental and *extra-Ego reality* exists and can be perceived, we must scrutinize and interpret the facts.

1. *Data Concerning Extra-Mental Reality.* Our body is such a reality, and it is clearly perceived to possess 'extensivity.' It is revealed to us as 'extra-mental,' but an integral factor in the process of sense-perception. Mind and body belong to the Ego and form a unitary principle of action.

2. *Existence of Extra-Mental Reality.* Realism, which accepts the existence of the human body, is in agreement with the facts of everyday life and with the findings of science. Consciousness gives direct evidence of the reality and existence of our body.

3. *Perception of Extra-Mental Reality.* It is possible, because the 'subject of knowledge' is not the unextended mind as such, but the Ego. The perceptive act is vital, but extended, demanding a vital and extended organism as its subject. Such is the Ego and, since the body is an integral part of this organism, it should be capable of concretely perceiving the body as an extra-mental reality. Descartes' antithesis is based on the fallacy of 'definition by initial predication.'

4. *Data Concerning the Non-Ego World.* They reveal 'externality' and 'otherness' in objects. Touch shows them as external to our body. The active influence of such objects on our body shows them to be extra-Ego.

5. *Existence of Non-Ego World.* Daily life and science demand that we accept the non-Ego world as real. Our passivity in receiving impressions proves that they are produced in us by 'outside' things; this alone accounts for their persistence, regularity, order, and compulsory perception.

Other minds exist. This is proved by language, which conveys new ideas to my mind; my consciousness testifies to the fact that they do not originate in my own mind. But 'other minds' — whose existence is admitted by idealists — are non-Ego realities.

6. *Perception of the Non-Ego World.* Extra-Ego objects can be perceived because our body, being a psycho-physical reality, is the *epistemological bridge* between the mind and the world. Through touch I perceive my own body as 'identical with self' and other bodies as 'non-identical with self'; this is due to their commensurateness and corporality.

Realism is thus critically established. We have vindicated the spontaneous conviction: *The reality and existence of our body and of the extra-Ego world is a fact; and both are perceived as they are in themselves.*

Chapter 11

REPRESENTATIVE AND PRESENTATIVE REALISM

REALISM, WHICH CONTENDS THAT EXTRA-MENTAL AND EXTRA-EGO reality exists and can be known by the human mind, must be accepted as the only true and valid theory of human knowledge, because it alone gives an adequate interpretation of the facts and data revealed by our consciousness. By accepting realism, however, as a general theory, the problem of the validity of human sense-knowledge is not completely solved. There are rival theories of realism. Realists are not in accord as to the manner in which the mind receives its knowledge of the external physical world through sense-perception. Due to their divergence of views in explaining the manner in which the mind effects its knowledge, realism appears in two radically different types: *representative and presentative* realism. These will now have to be examined and evaluated.

TYPES OF REPRESENTATIVE REALISM

Representative realism (mediate realism, hypothetical realism, cosmothetical realism, inferential realism) is the theory which maintains that the human mind is immediately

aware, not of the external objects themselves, but of its own *internal 'representations' only*, from which it then *infers* the existence of external, non-Ego reality as their cause. Representationists accept, of course, the existence of an external, physical, extra-Ego world, otherwise they would not be realists; but they claim that we are incapable of 'perceiving' it in any way directly and immediately by means of intuitive sense-perception. We have only subjectively produced images or 'representations' in our mind. The mind perceives these images or representations and, since it is aware that it is not their sole cause, *reasons* to the existence of an outside world as their physical cause. The existence of the non-Ego world is thus a matter of inference on the part of our intellect; hence the name 'inferential' realism. And since this gives us no immediate but only a mediate knowledge of the world, we have 'mediate' realism. The world is simply assumed as a necessary hypothesis, in order to give an adequate explanation of the data of sense-perception; therefore the term 'hypothetical' or 'cosmothetical' realism. In any case, we never perceive directly anything but our own internal mental representations, and these are produced partly by the outside objects and partly by the subjective action of the perceiving mind. The question naturally arose: Is there any *resemblance* between these 'representations' and the extra-mental and extra-Ego objects which they represent? The answer led to two main kinds of representative realism: subjective and objective.

According to *subjective* representationism our knowledge of the existence of an extra-mental universe is

mediate, indirect, inferential; we know that extra-mental reality *exists*, but that is all we know. What the objects in this universe really are like in nature, is beyond our knowledge, because our 'representations' of these things are merely 'mental images' or 'symbols.' These images or symbols bear no resemblance whatever to the objects they 'represent'; they resemble them no more than the printed words on a page are similar to the things for which they stand. The outside reality itself is absolutely *unknown* and *unknowable*; we can only know that *something exists* which produces this subjective image in us. The 'representations' of our perception are indeed caused by external objects, but they tell us nothing about the reality of the objects which cause them. Such is the view of the hypothetical dualists of modern epistemology. Since, however, this class of representationists admits the existence of some sort of extra-mental and extra-Ego reality, they claim that their theory is a genuine form of realism.

The *objective* representative realists agree with the preceding class of philosophers in contending that what the mind immediately perceives is the mental image or 'representation'; and from this 'representation' they also *infer* the existence of an outside world. But they differ from 'subjective' representationists in claiming that the mental images or 'representations' resemble the objects which cause them. They base this *resemblance* on the Principle of Causality. They argue that an effect must resemble its cause. All operations proceed from the nature or essence of a thing; different natures, then, will produce different kinds of operations. Consequently, the kind of operation will

reveal the kind of nature from which it springs. And thus, from the effects of these operations we can logically infer the qualities of the nature operating. Applying this principle to the case of sense-perception, they contend that the 'representations' produced in the mind by external, physical objects enable us to draw a legitimate inference to the qualities and nature of the causes which produce the 'representations' in us. In this manner, these 'representations' are truly 'images' of the things outside and much more than mere 'symbols' of them. The knowledge thus acquired contains genuine information regarding the extra-mental and extra-Ego world, even though we have no immediate perception or intuition of the objects themselves. This view of sense-perception is held by many neo-scholastic philosophers, like *Mercier*,¹ *Jeannière*, and others. Some *critical realists* belong to this class. According to them, the mind perceives the 'essences' of things, not the things themselves; but these 'essences' resemble the nature of the individual realities.

SUBJECTIVE REPRESENTATIVE REALISM

We group in this class all those theories which, while maintaining the fundamental idealist principle that the mind cannot transcend its own conscious states, accept the existence of an extended, material reality as the hidden and unknown cause of our sense-perception. Such are, for instance, Kant's phenomenalism and Spencer's 'transfigured realism.' There are, of course, many variations of this general theory of representative realism, but they all

agree in this that they are a form of *hypothetical dualism* and realism; they *postulate* the existence of extra-mental and extended things, claiming at the same time that the human mind can have no knowledge or perception of them. Such a realism is no realism at all; it is a disguised and veiled idealism. These philosophers intend to be realists, but they could not escape the net of idealism.

The proof of this has already been given in our examination of extra-mental and extra-Ego reality. According to subjective representationism we can know only our own conscious states. All perception of extension and extended objects is merely a conscious state. Therefore, they say, all such perception is nothing but a modification of our mind and reveals nothing of the qualities and nature of the objects themselves.

If this were the case, our knowledge of our body (extramental reality) and of the external world (extra- Ego reality), as proved in the preceding chapter, would be purely of an *imaginary* and *subjective* character. And since, according to these thinkers, this knowledge tells us nothing whatever about the things-in-themselves outside the mind, this knowledge is illusory. Our *intellectual* knowledge, however, is based on this sense knowledge, and as such must also be illusory. What value, then, can our knowledge have? It is all a mental construction, a subjective fabrication. That this would destroy the validity of all our knowledge, must be obvious. Skepticism is inevitable.

Practically all subjective representationists, unless they are thoroughgoing idealists, speak of the *brain* and brain-conditions, *nerves* and neural currents, *sense-organs* and

sentient experiences. But what meaning have such terms and phrases except that they refer to a real body with the side-by-sideness of extended, material parts? If the body is real, we know a great deal about the 'extra-mental' body and its operations, and representationism refutes itself; and if the body is not real, these philosophers are illogical and inconsistent in speaking of such things and building their theory upon them.

The adherents of subjective representative realism admit that *some form* of extra-mental and extra-Ego reality *exists*. Most of them are even willing to concede that this reality consists of a multiplicity of things; they are pluralistic. Some lean toward the notion of a vague 'world stuff,' 'mind-stuff,' or 'neutral stuff,' very much akin to the Absolute of the more pronounced idealists. But whether their conception of extra-mental and extra-Ego reality be pluralistic or dualistic or monistic, they thereby claim to know *more* about this reality than *its mere existence*. This, however, is inconsistent, because their fundamental position is thus relinquished.

Besides, on what grounds do they acknowledge the existence of this reality? On the grounds of causality: these things or this reality is the cause of our perceptions. But if the Principle of Causality enables them to infer this existence, why should this same principle not enable them to infer *more* than the mere existence? One can see no logical reason why it should be restricted to this one fact alone. If representationists were consistent with the tenets of their theory, they could not conclude legitimately even to this fact of existence, because in this knowledge they

actually *transcend* their own conscious states; they do know something which lies *outside* the confines of their mind. Again, if all our knowledge is purely mental, then the Principle of Causality is also nothing but a purely mental product; as such, this principle would demand only a *mental cause* for our perceptions. For them to apply a principle of the mental and ideal order to the real and physical world is, according to their own theory, an illogical and unwarrantable procedure. What, then, is left for them but an unmitigated idealism which must eventually end in solipsism? But that would be intellectual suicide.

Representative realism is the outcome of empiricism, and empiricism is the philosophic offshoot of *science*. Above all things, these philosophers want to be scientists and be in accord with science. We agree with them in the view that science must furnish the groundwork, the raw material, of philosophy. But science is by no means a champion of subjective representative realism. On the contrary, science absolutely demands extra-mental and extra-Ego reality, not only as far as its existence is concerned, but also as regards the *nature, qualities, and operations* of the extended, physical *objects* as we know them. Or would anyone seriously assert that the laws of science are only 'mental' laws which regulate the relations of 'symbols,' 'ideas,' and 'representations' of the mind? Do they not apply, according to the intentions of scientists, to actually existing objects of a real, material universe? The *scientists themselves* certainly are convinced that they are dealing with extra-mental and extra-Ego realities that have an existence of their own, independent of the mind that conceives and

knows them. Subjective representative realism is thus seen to be contrary to all suppositions and conclusions of science. If these things are not real, science loses all meaning and purpose. But a theory that is so subversive of the fundamentals of exact science, must be fallacious.

Subjective representative realism is nothing but a half-hearted idealism and therefore no realism at all. It cannot explain the facts and must be rejected.

OBJECTIVE REPRESENTATIVE REALISM

While *objective* representative realism agrees with subjective representationism in admitting that the mind perceives directly and immediately only 'images' or 'representations,' from which it then infers the reality of extra-mental and extra-Ego objects (the human body and the universe), it differs radically from it in contending that these 'images' or 'representations' bear a *resemblance* to these objects and thereby give us a genuine knowledge of their being. They base this contention, as we have seen, on the Principle of Causality.

The question then arises: *Must effects 'resemble' their causes?*

If so, the theory can be considered valid; if not, our knowledge of the external world is no better than that of subjective representationism, which is, as we have just noted, only idealism in disguise. The whole matter, then, resolves itself into this: Does the fact of causality always imply a *similarity* between cause and effect, so that a knowledge of the effect (the representations' here)

automatically gives us a knowledge of the nature and being of the cause (the extra-mental and extra-Ego objects)?

Experience tells us beyond reasonable doubt that effects do *not* always resemble their causes; in many cases there is no similarity whatever between the two. Our daily contact with causality shows plainly that effects are of two kinds: *univocal and equivocal*. 'Univocal' effects are those which are *similar in kind* to the causes which produce them. We see innumerable instances of this in nature. Plants, animals, and men reproduce their own kind, and here the effects are certainly similar to the causes. Horses produce horses, cows produce cows, eagles produce eagles, man produces man, and so on, throughout the entire kingdom of living beings: the offspring (effect) resembles the parent (cause). These are univocal effects similar to their causes.

'Equivocal' effects, on the other hand, are *dissimilar in kind* to their causes. The world is also full of these. The music (effect) of a pipe organ in no way resembles the pipes, the mechanism, the organist, the air (cause). The destruction caused by a shell hitting a building has no similarity to the shell, the exploding powder, the gun, or the gunner. A piece of sculpture representing a horse carries no resemblance to the chisel or the sculptor.

Bearing this in mind, we are now in a position to pass judgment on the validity of the theory of objective representative realism. The main contention, that the 'images' or 'representations' of extended material objects bear a real resemblance to these objects, is *groundless* and *gratuitous*. These 'representations' are produced by external objects, but what guarantee can they give us that

these 'representations' are *univocal effects*? This is, from what we have seen above, certainly not self-understood; because an effect might be either univocal or equivocal, and there is nothing to show why these 'representations' must be, or will be, univocal rather than equivocal. And if they should happen to be equivocal, their 'resemblance' to the external objects is gone, and then we know nothing about what these external objects are in themselves.

The *only* things the mind can perceive are the 'images,' the 'representations.' They *may* resemble external objects, but they may also, as far as we can tell, be totally unlike the external objects which produce them. Our mind must be forever in doubt on this score. Our knowledge of the external world loses all certainty, and we are again on the threshold of idealism and skepticism.

Objective representative realism thus offers no solution for the problem of the validity of human sense-knowledge. It also is but a veiled and disguised form of idealism and as such is erroneous and fallacious. What, then, is the outcome of our present investigation? Just this: every form of representative realism, whether subjective or objective, restricting the human mind to a knowledge of its own internal conscious states and denying a direct perception of extra-mental and extra-Ego reality, is no realism at all, but only a disguised variant of idealism.

PRESENTATIVE REALISM

Presentative realism (immediate realism, intuitive realism, natural realism, perceptionism) is the theory which

maintains that physical, external objects are 'presented' *directly in some form* to consciousness in sense-perception, so that their reality is perceived *as it exists in itself* 'out there' in nature. In this. View the objects are 'present' or 'presented' directly to the mind through the medium of the senses; hence the term 'presentative.' The external object itself is 'immediately' the object which is 'perceived' or 'intuited'; this explains the terms 'immediate' and 'intuitive' realism and 'perceptionism.' And since it is 'natural' for man to think that he actually perceives the objects themselves as they are 'out there in nature,' this theory is also called 'natural' realism. The fundamental thought in presentative realism is that the *objects themselves, in some form or other*, are directly perceived in sense-perception. Because of the active influence of both object and mind upon the sense-process, it is natural that some realists will give a more 'objective' and others a more 'subjective' interpretation of the facts involved. And thus two rival theories have been advanced to account for our experiences: rigid or naïve presentative realism and moderate or critical presentative realism. The difference between these is one of degree, not of principle.

Rigid or *naïve* perceptionism is the realism of the ordinary man and of the philosopher who is convinced that the things he perceives are actually in nature as they *appear to his senses*. If he sees a colored object, the color is really 'outside' in the thing, just as he sees it. Sounds are real tones emitted by the sounding object, just as he hears them with his ear. And all objects are extended, have a definite shape, and are at rest or in motion, just as he

experiences them through one or more of his senses. In other words, *all qualities are objectively real as perceived*.

Critical or *moderate* perceptionism claims that some qualities of objects are 'objectively' real and as such are perceived immediately and intuitively by the senses; other qualities are not present in the object as such, independent of the sensing subject, but exist only *potentially* or *causally* in the objects. Thus, extension, shape, motion or rest, unity or multiplicity, would be considered 'objective' qualities inherent in the bodies themselves, independent of sense and mind, and as such would be directly perceived. But color and sound, for example, do not exist in the objects themselves as 'color' and 'sound'; these are 'subjective' qualities which exist only in the perceiving senses, with this distinction, however, that they are causally produced in the senses by vibrations coming from the objects 'out there' in nature. In order to understand the problem better, it will be necessary to explain the various kinds of sense-qualities.

It has become customary to divide the sense-qualities of objects into *primary* and *secondary*, or as Aristotle and the scholastics did, into *common* and *proper*. Any object, quality, or feature of reality, which can be perceived by a sense, is called a 'sense-object,' 'sensile,' 'sensible,' or 'sense-quality'; they all mean the same thing. Now, some of the sensibles or sense-qualities can be perceived by a single sense only. Thus, the organ of sight alone perceives colors; the organ of smell alone perceives odors; the organ of hearing alone perceives sound: such qualities are *proper or secondary* sensibles. Other sensibles or sense-qualities can be perceived by *more than one sense-organ*. Extended

surface, shape, volume, number (i.e., whether one or many), rest and motion, can be perceived by at least two of the senses, sight and touch: they are common or primary sensibles.

And this brings us to the very heart of the controversy waged between rigid and critical perceptionism: *Are all sense-qualities 'objective' or are some of them 'subjective'?* Rigid or naive perceptionism stands for the theory that all sensibles are 'objective'; they are really in the objects as perceived. Moderate or critical perceptionism, on the other hand, claims that the common sensibles are really in the objects as perceived, but the proper sensibles are more or less 'subjective' in character.

THE CASE OF RIGID PRESENTATIVE REALISM

The rigid realist occupies a naturally strong position, for he has practically all humanity to support his view. The man in the street, undisturbed by the findings of science and the psychological difficulties involved in sense-perception, is a naive realist who is thoroughly convinced that he directly perceives all extra-mental and extra-subjective objects as they *really are in themselves*. The philosopher, who is a rigid perceptionist, is not so unreflecting and unscientific; he knows that he cannot take things for granted and that many objects do not always 'appear' as they 'really are.' Still, while he is fully aware of the many philosophic difficulties inherent in rigid realism, he places himself frankly on the standpoint that all sense-qualities, primary and secondary, are intuitively perceived as they 'really are'

in nature, provided the *normal conditions* of sense-perception are present. If conditions are abnormal, errors will be committed; if they are normal, errors can be eliminated. These conditions pertain to the 'sentient subject,' to the 'sensed object,' and to the 'medium' intervening between the object and the subject.

As far as the *sentient subject* is concerned, it is necessary that the sense-organs be free from organic and functional defects. If any of the senses are abnormally constructed or if their proper function is impeded in any important degree, it will be but natural that they cannot register the data properly; distorted perceptions will result, and errors of judgment will be the inevitable consequence. The case would be similar to using defective instruments or tools in highly specialized crafts. Regarding the *sensed objects*, they must be placed at the right distance and in the right setting. Every sense has its own definite field of operation; within this field its efficiency is high, and beyond this field it is low or even nil. A specific relation exists between object and sense, and this relation cannot be appreciably disturbed without incurring the risk of faulty perception. The *medium* intervening between object and sense must also be normal, otherwise perception cannot be normal. A change of the medium will naturally bring about a change in the relation between the object and the subject, with the result that the perception of the object will be distorted. An oar partly submerged in water will appear bent, because a part of the rays of light reaches the eye through the medium of air alone, while the other part reaches it through air and water. In a similar manner, due

to the refracting action of the atmosphere at the horizon, the morning sun is seen before it actually rises above the earth's rim, and it appears red and much larger than it really is; variations in the density of the atmospheric medium account for the phenomenon.

It is unquestionable that the *normality of conditions* is an important factor in true sense-perception. Given the presence of normal conditions, the rigid perceptionists claim, our senses must be considered reliable within the sphere of their proper function and enable the intellect to draw proper conclusions from the data presented by the senses. To deny this would mean that our normal senses under normal conditions would give us a false and illusory picture of the world around us; and that would be tantamount to the assertion that *illusion and error* would be the *normal result* of our faculties in their *normal and natural operations*. Such an assertion, however, would inevitably lead to general skepticism, because neither our senses in their normal operations nor reason in its legitimate conclusions could be trusted. That, of course, would be the bankruptcy of all knowledge, and science and philosophy would be hopeless and useless occupations. But this is evidently absurd. Consequently, our senses under normal conditions must be reliable sources of information concerning the extra-mental and external world. If errors occur, they are only incidental and accidental and can be avoided by careful and thoughtful attention to the data.

This general principle the rigid perceptionists then apply to the perception of *sense-qualities*. And they argue in the following fashion. "There are innumerable instances in

which we act with deliberate attention and with a knowledge of the essential normality of our senses. In applying our senses to an object, we are conscious that *all* our sense-perceptions testify with equal force to the existence of certain qualities in the single bodies, namely, motion or rest, volume, shape, and distance. The conjunction of these conditions, however, entitles us to pass a judgment on the sense-qualities of the single bodies, because we thereby find ourselves *forced* to pass this judgment, and we consider any serious doubt to be unreasonable. If our judgment, notwithstanding this compulsion, were false, we would be subject to error out of necessity and would have to despair of all certitude. In special and definite instances, therefore, Our reason is capable of judging with certitude on the sense-qualities of bodies.

“With regard to the particular case of the so-called *secondary* sense-qualities, there can be no doubt that our subjective sense-perceptions, if we presuppose the existence of bodies, will find their adequate explanation in nothing but the specific qualities of bodies through which the latter act upon our senses. For even the existence of bodies could not be known to us except by means of those qualities in virtue of which the bodies appear to us as colored in this or that way, as having this or that taste or odor, or as being hard or soft. To deny or doubt the trustworthiness of our senses in the perception of these qualities would therefore be as much as to question the possibility of a knowledge of the *bodies* themselves.”²

Immediate intuitive perception of sense-qualities we certainly have. Then why make a distinction between primary and secondary sensibles at all, some of which are supposed to be 'objective,' while others are considered more or less 'subjective'? There seems no reasonable cause in the *qualities themselves* to judge any of them to be more subjective or less objective than the others.

Furthermore, humanity in general has the spontaneous conviction that *all* sense-qualities, primary and secondary, are found in the objects as they appear in perception. This is the verdict of *common sense* and therefore of *natural reason*. Can all humanity be wrong in a matter which is so interwoven with daily experience of the most intimate character? If so, is human reason then not unreliable? And if unreliable, is not every philosophical theory then just sheer waste of time and energy? If we impugn the reliability of reason and our senses, must we not end in the bog of skepticism? We must remember that the constant and universal conviction of mankind gives *presumptive evidence* of tremendous force to this view of the objectivity of all sense-qualities without exception. This theory explains the facts so fully and convincingly that it amounts practically to a *scientific and philosophic law of nature*.

ANSWER OF CRITICAL PRESENTATIVE REALISM

As far as the arguments of the rigid realists are concerned, the critical perceptionists subscribe to them, considering their general trend and import. But they deny that the arguments prove that *all sense-qualities* without exception,

primary and secondary, must be accepted as *objectively present in the objects* 'out there' in nature just as they 'appear' to the senses. This conclusion exceeds the premises. The argument merely proves that *in general* immediate, intuitive perception of the external, physical qualities of objects is the correct theory of knowledge, but it does not prove that all sense-qualities in particular are intuited as objectively present in the things themselves. To argue from the 'general' truth of a statement to every 'particular' instance and case which apparently falls under it makes them guilty of the fallacy of passing from an 'absolute' to a 'qualified' statement. Certainly, if the argument were as exclusive as the rigid realists assert, the question would be definitely settled; but that they have not proved. After all, the question is a matter of *facts* properly interpreted. The facts are the same for everybody, and no one denies them; but the interpretation of these facts is a different affair, and reason is the arbiter there.

We must always bear in mind, that the *senses* themselves *do not judge*: they merely report the presence of certain sense-impressions. It is reason, and reason alone, which judges whether anything 'objective' corresponds outside in nature to the subjective sensations and perceptions thus recorded by the senses. Truth resides in the judgment, and judgment is exclusively the function of the intellect. The senses can do no more than present the data, which reason must then interpret according to its own lights. And if reason, after a careful scrutiny of the data of sense-perception, is forced to judge that certain sense-qualities are not objectively present in nature as perceived

by the senses, we must accept the dictates of reason as final. Any other course would be unscientific and unphilosophical and would be bound to lead ultimately into error. General statements will not settle the issue; facts alone can. So let the facts speak for themselves.

Again, rigid idealists assert that the *secondary* qualities of bodies must be objectively present in them; otherwise we would not know even of the *existence* of bodies themselves, and thus the possibility of a knowledge of the *bodies* themselves would be called in question. They are wrong, for they prove too much and therefore nothing. Both rigid and critical presentationists consider the primary qualities as perfectly 'objective,' as really existing *in* the bodies as they are perceived by the sense of touch. It is through these qualities that the existence, extension, shape and voluminousness of bodies are observed in sense-perception. Here we have the essential guarantee of the reality of external bodies, and this guarantee is not invalidated by the assumption that the secondary qualities are not actually present in the bodies as perceived.

Furthermore, rigid perceptionists maintain that there is no foundation in nature for making such a radical distinction between primary and secondary qualities. Again they are wrong. Nature itself gives us the ground for making this distinction. The primary qualities are in themselves more fundamental in character than the secondary. To have definite shape, volume, weight, and impenetrability, flows necessarily from the extension of bodies. There could be no colors, sounds, odors, flavors, temperature, and resistance, if these primary qualities

were not present *before* them, since these secondary qualities need extended surface in order to exist and be what they are. The primary qualities can exist without the secondary, but the secondary cannot subsist without the primary. And then, too, the very nature of the perceptive act provides a reason for this distinction. The primary qualities are perceived by *direct contact* between our body and other bodies through the immediate perception of the sense of touch. Herein lies the ultimate assurance that these bodies and their fundamental qualities are real and objective. Other qualities, like color, sound, etc., are perceived, not through direct contact, but through some 'medium' distinct from the bodies and distinct from the qualities themselves, namely, vibratory motions of ether, air, and so on. Hence, it is false to assert that there is no natural distinction between the two sets of qualities and that bodies could not be known unless the objectivity of secondary qualities were also admitted. It might, then, very well be that the latter are more or less subjective, while the primary qualities alone are objectively present in bodies, without destroying the essential validity of sense-perception.

Finally, rigid perceptionists appeal to the spontaneous conviction and the common-sense judgment of mankind; all men, they say, consider the secondary as well as the primary qualities to reside in the objects as perceived. In answer to this, critical perceptionists maintain that this argument is of very dubious force, because this conviction is *not* at all as *universal* as claimed. In fact, it was the natural philosophy of the ordinary man which coined the phrase

that “appearances deceive.” This implies the well-grounded *judgment* that things are not always as they ‘appear’ to the senses. He corrects many sense-impressions through the judgment of his reasoning faculties, so that he is by far not as ‘naïve’ as many people think. He would never dream, for instance, of accepting the *diminishing perspective* of objects, as seen in his visual picture, as a literal transcription of reality; and that is a very vital point in visual perception. Nor does he believe in the actual *shifting of position* among objects, relative to each other, as he witnesses this phenomenon while traveling in a train or riding in his car, although that is what his eye shows him as clearly as anything else. He is Very wary regarding the *real color* of objects, especially when viewed under different kinds of light, even though his eye can make no distinction between the ‘objectivity’ of the varying color perceptions under changing sources of illumination, he knows that a suit of clothes, which he examines, may appear black under electric light and yet be blue in sunlight. He is aware, too, that there is a considerable element of *subjectivity* in many of his sense-reactions. Sweet wine, for instance, always tastes sour to him after eating sugar, while dry wine appears sweet after lemon juice; he experiences chills of coldness throughout his body, so that his teeth chatter, although the temperature of his body is much higher than usual. Hundreds of similar examples could be adduced which manifest his conviction that things are frequently quite different in reality from what they appear to be according to the testimony of his senses. If he is not fully conscious of the corrective judgment of his interpreting

reason in these and similar cases, this is due to the *habitual action* of lifelong experience which enables him to interpret these deceptive appearances correctly without being aware that he is doing so. All of which shows that the spontaneous convictions of the ordinary man do not favor rigid realism as much as is claimed.

Such is the answer of the critical perceptionists to the arguments of the defenders of rigid presentative realism. Their answer so far is *negative* in intent, showing that the opposing arguments lack cogency. More than this, of course, is required in order to prove that critical, and not rigid, presentative realism deserves to be classed as the only theory of sense-perception which explains all the facts. *Facts must prove or disprove a theory.* And critical perceptionists produce a formidable array of facts from science and from everyday life which, according to their view, furnish positive and incontestable proof of the truth of their theory. These facts, at least in their main outline, will now have to be considered.

SUMMARY OF CHAPTER XI

There are two main realist theories: representative and presentative realism. Both claim to be a genuine form of realism, capable of explaining all the facts.

1. *Representative Realism*. It is also called mediate, hypothetical, cosmothetical, or inferential realism. It maintains that the mind is immediately aware, not of the external objects themselves, but of its internal 'representations' only, from which it then infers the existence of external reality as their cause. It is *subjective* representationism, if it contends that these representations are mere 'symbols' of reality, without any resemblance to it. It is *objective* representationism, if it contends that these representations actually resemble the external objects which are their cause, thus giving us a genuine knowledge of these objects.

2. *Subjective Representative Realism*. If this theory were correct, our knowledge of our body and of extra-Ego reality would be imaginary and illusory. For these thinkers to speak of the brain, nerves, and sense-organs is an admission that we can and do know 'extra-mental' reality. They are inconsistent in restricting the Principle of Causality. Their position is contrary to science, because scientists are convinced that their findings refer to a real extra-mental world.

3. *Objective Representative Realism*. Effects may be univocal or equivocal, i.e., similar or dissimilar in kind to the causes. Experience shows that there are many equivocal

effects in nature; they do not resemble their causes. Hence, the fact of resemblance must ever remain doubtful. All representative realism is disguised idealism.

4. *Presentative Realism*. It is also called immediate, intuitive, natural realism, perceptionism. It maintains that physical objects are 'presented' directly in some form to consciousness in sense-perception. *Rigid* or *naïve* perceptionism contends that all sense-qualities are objectively real as perceived. *Critical* or *moderate* perceptionism contends that some qualities are objectively real as perceived, while others are only potentially or causally in the objects.

5. *The Case of Rigid Perceptionism*. The general proof is as follows. Given the presence of normal conditions, our senses must be considered reliable; otherwise illusion and error would be the normal result of our faculties in their normal and natural operations. Applying this general argument to secondary qualities, rigid perceptionists claim that we could know nothing of bodies, not even their existence, if these qualities were subjective. Both primary and secondary qualities are equally 'objective' to the senses. It is the verdict of common sense and therefore of natural reason, that all qualities are objective; this amounts practically to a law of nature.

6. *Answer of Critical Perceptionists*. The argument is too general; it merely proves that some qualities must be objective. The reality and existence of external bodies is guaranteed sufficiently by the primary qualities. Primary qualities are more fundamental than secondary; nature itself makes this distinction. The common-sense conviction

of mankind is not as universal as claimed; in their daily life men frequently show that they do not consider things to be objectively real as they are subjectively perceived.

Chapter 12

CRITICAL PRESENTATIVE REALISM

IN DISCUSSING THE FACTS OF SENSE-PERCEPTION, WE DEAL WITH ultimate experiences of the human subject, and we must distinguish closely between the facts themselves and the interpretation of these facts. The facts are registered by the senses, but the senses tell us nothing of the 'nature' of these facts: it is the interpreting intellect which gives us an insight into their being. It is the duty of the philosopher to study the facts of everyday life and of science and to draw the conclusions necessarily implied in them. The facts must dictate the theory which attempts to explain them; and any theory which fails to give an adequate account of all the facts of the case must be relinquished in favor of the one which does.

THE PROBLEM OF SECONDARY QUALITIES

Rigid perceptionists and critical perceptionists agree that the *primary* qualities of objects (extension, shape, unity and multiplicity, rest and motion) are objectively real and are perceived as such. The difference between them centers in the problem of the *secondary* qualities (color, sound, odors,

flavors, etc.). Rigid perceptionists contend that all primary and secondary qualities are *objective* and *absolute* in the sense that they exist 'out there' in nature, independent of, and antecedent to, the act of perception; they are present and remain present in nature, even if there be no sense-organ in existence to perceive them. Critical perceptionists distinguish between the two classes of qualities and contend that the secondary qualities do not exist 'out there' in nature as such, objectively and absolutely, but are *subjective and relative*, in the sense that they exist only in the act of sensation of the perceiver; secondary qualities, therefore, do not exist independent of, and antecedent to, the act of perception. However, these secondary qualities are not 'purely' subjective and relative, because their causes, namely, the bodies and their properties, exist and through their influence produce these sensations of color, sound, etc., in the perceiver. According to critical perceptionists, then, secondary qualities are 'causally' and 'potentially,' but not 'actually' and 'formally,' present in the bodies. When speaking of the 'objectivity' or 'subjectivity' of secondary qualities in the following discussion, the terms must be accepted in the meaning here designated.

The controversy concerning the nature of the secondary qualities has been very keen among philosophers in modern times, especially among the *scholastics*. This is due mainly to the findings of science. Scientists in general favor the subjectivity of these qualities, as will be seen by consulting the standard works of psychology, physics, physiological psychology, and experimental psychology.¹

The older medieval scholastics considered all qualities as *formally* present in the objects themselves. Redness, for instance, is a physical accident of the rose itself, independent of light; sugar is sweet in itself; ice is cold in itself; a bell really emits a sound. Others distinguished between 'formal' and 'fundamental' qualities. According to them, color and sound as such (and all the other secondary qualities) are not present in the object itself, but in the *medium* which intervenes between the object and the sense-organ; light is colored and air is sounding. This view places color and other qualities *fundamentally* in the objects and *formally* in the medium; but as such they are objective and absolute, independent of, and antecedent to, the perceiver. Among the older prominent scholastics who favored this theory are *St. Albertus Magnus, St. Thomas Aquinas, and Suarez*.

Neo-scholastics, generally speaking, seem to lean toward that form of rigid perceptionism which distinguishes between 'formal' and 'fundamental' qualities. Among those who adhere to the objectivity of secondary qualities as independent of perception may be mentioned: M. Liberatore, C. Sanseverino, T. Zigliara, Z. Gonzalez, F. Seewis, L. de San, M. Glossner, T. Pesch, E. Commer, B. Loranelli, A. Farges, G. Lahousse, I. Straub, M. Schneid, van der Aa, S. Schiffini, J. Urráburu, L. Lercher, O. Willmann, C. Willems, C. Boetzkes, P. Gény, A. Michelitsch, de la Vassière, A. Seitz, C. Frick, Lehmen-Beck, J. Maritain, J. Gredt, G. Esser, P. Coffey, and others.

Other neo-scholastics are *critical perceptionists*. They claim that the secondary qualities have only a *subjective*

existence in the perceiver, so that their formal being is dependent on the act of perception; as such, then, they exist neither in the objects nor in the intervening medium.

The chemico-physical properties of things, however, are the cause of their production, in as much as the energies of objects influence the sense-organs effectively and through their stimuli produce therein the sensation of color, sound, etc. Among those who defend this view are: D. Card. Mercier, C. Gutberlet, J. Balmes, A. Stöckl, J. Pohle, G. Hagemann, M. Maher, M. Domet de Vorges, J. Linsmeier, P. Fournier, D. Palmieri, S. Tongiorgi, Ch. Lahr, J. Fröbes, P. Balzer, Mattiussi, de Sinéty, H. Gruender, Necchi, P. Siwek, and others.

Critical presentative realists maintain that the facts clearly show the secondary qualities to be subjective in character; i.e., they are not independent of, and antecedent to, the act of sensation, otherwise *contradictory attributes* will have to be predicated of the same object in the same respect. In support of their view, they appeal to experience and science.

TOUCH, TASTE, SMELL, AND HEARING

Touch. 'Heat' and 'cold' are secondary qualities and, to all appearances, are objectively present in the things which come in contact with our body. But *temperature is relative* to the perceiver. If man's body temperature be taken as 'physiological zero,' any object of the same temperature will evoke no thermal experience; but anything below this zero will appear cold and anything above it will appear warm or

hot. As the body temperature is heightened or lowered, objects will change from hot to cold and vice versa, although nothing was done to change their temperature. Thermal impressions also depend upon humidity. Evaporation from the skin gives the impression of coolness; but if the surrounding air is humid, so that evaporation is impeded, we have the sensation of increased heat, although the temperature is the same. Increased temperature of the air increases its capacity to absorb moisture; hence, even though the temperature of the air be increased, we experience the sensation of greater coolness. Similarly, agitation of the air around the body, for instance, by means of a fan, produces the sensation of coolness, although the temperature of the air has not been changed. If we place the right hand in a vessel of water of $+60^{\circ}$ and the left hand in a vessel of water of $+100^{\circ}$ and then place both hands in water of $+80^{\circ}$, the same water will appear warm to the right hand and cool to the left.

According to science, the sensation of heat is due to electromagnetic radiation. The closer we move to its source, the hotter the object seems to become; and the farther away we move, the less we experience of its heat. If heat were really objective, in the object itself or in the intervening medium, then the space between the sun and the earth should be filled with 'objective heat'; and this heat should be more intense above the earth in the direction of the sun. This, however, is not the case: the temperature decreases as the altitude increases, and interstellar space, according to science, is hundreds of degrees below zero.

From this we must conclude that the experience of heat is a subjective reaction of our nervous system.

Taste and Smell. All people are aware that taste is a capricious sense and that 'there is no accounting for tastes.' Taste and smell are physiologically closely related, and many experiences which we attribute to taste are really due to the sense of smell; the confusion is remarkable. The same substance may produce a different taste, depending on what part of the tongue it is placed. Passing from the tip to the base of the tongue, the following changes of quality have been shown by experimentation to take place: sodium chloride changes from salty to slightly bitter; potassium chloride changes from salty to sweet; alum, from sour to sweet; bromo-saccharine, from sweet to bitter. Distilled water, after a solution of hydrochloric or sulphuric acid, tastes sweet. A weak solution of quinine sulphate, after sulphuric acid, tastes sweet at the tip of the tongue and bitter at the base. Objects, however, cannot be objectively sweet and bitter at the same time or change objectively, because of their mere position on the tongue.

It is a common experience that certain substances are delicious to the taste or smell of some persons and nauseating to the taste or smell of others. If flavors and odors were objective qualities, all who can taste or smell should perceive the same objective qualities. The qualities certainly do not change objectively in themselves, simply because different persons perceive them. Men and animals perceive entirely different flavors and odors in the same object. If they taste the same objective flavors and smell the same objective odors, there should be no difference in their

reactions. There is, however, a great difference, and this can be adequately explained only on the supposition that flavors and odors are not objective qualities of the objects themselves, but are chemical properties which produce effects according to the subjective character of the perceiving organs.

Hearing. Sound is also supposed to be objective, independent of the organ of hearing. A bell, for instance, emits a sound which corresponds to the note 'c' on the scale. No matter how often we strike the bell, the note will always be the same. Let it be assumed that a bell is clanging at a railway crossing and that its note is 'c.' Here, then, there is nothing to alter the note; the bell continuously emits 'c,' and anyone standing near by hears this identical note as long as the bell rings. However, every person in a rapidly moving train will hear the pitch of the bell rise as they near the bell, and they will hear it sink as they move away; it is only in the immediate vicinity of the bell that they hear the note as 'c.' Everyone in the train, from the engine to the last car, hears a different tone, ranging, for instance, from 'c' to 'e' and from 'c' to 'a' at the same moment of time, although nothing has happened to the bell to change its tone. If the 'objective' tone of the bell is 'c,' it should be physically impossible to hear a different tone, otherwise people would hear tones which are not present and not hear the one 'objective' tone which is present. That, however, is actually what is experienced: each person hears a different supposedly 'objective' tone. Consequently, sound is not objectively present in the bell; to

maintain its objective character involves the contradictory property of 'c' and 'not-c' at the same time.

Due to this characteristic of sound, many neo-scholastics place sound, not in the object itself, but in the air or intervening medium. This, however, will not save their position of rigid perceptionism. Persons standing within range of the stationary bell at any point will hear only 'c.' Let us suppose that the middle of the moving train is directly opposite the bell. Then every person standing near the tracks at the head of the train or at the end of the train will hear only 'c,' but every person within the moving train will hear a different tone, as explained above. If, then, the 'objective' tone in the air is 'c,' this tone must be the same wherever the sound happens to travel, and everyone must hear this tone 'c' and no other. That, however, is not the case; the tone is experienced as different by different persons. Consequently, formal sound is neither in the object nor in the air, but in the organ of hearing itself; in nature there are only vibrations of definite length and frequency which are then translated into sound by the individual ears in the act of sensation.

SIGHT: REFRACTION OF LIGHT

Nothing seems more obvious to us than that things are really colored and that color exists in the bodies themselves. This, however, is a matter of judgment, not of sense; the eyes merely report the facts of sight and tell us nothing about the actual reality of what they perceive. If a thorough scientific investigation of the data confirms the

theory of objectivity, we must, of course, accept the verdict of science; we must, however, also accept its verdict, if it can show that colors are not objective. This, critical perceptionists claim, science does.

Refraction produces results which are extremely difficult to comprehend and explain, if color is objectively present in objects. The phenomena of the rising and setting *sun* are familiar to everyone. The sun appears much larger than usual; it appears elliptical in shape; it appears as a deep-red or golden ball; it appears to become smaller in size as the morning progresses and larger as it sinks toward the horizon in the evening. We know that none of these things are actually so. The actual sun does not change in size, shape, and color from hour to hour during the day, but remains the same throughout the year. Were the sun 'objectively' red, why do we see it as white during the greater part of the day? Were it white, why do we see it as red in the morning and evening? Were either of the colors objective, we should see nothing but that one color all the time. Since the color changes continually in the unchanging sun, neither can be objective. This becomes even more obvious when we consider that people on different parts of the earth in the east and the west, looking at the sun *at the same instant of time*, receive entirely different impressions regarding its size, shape, and color: it is big and little, red and white, round and flattened, at the selfsame moment. But this is obviously impossible; the *real* sun cannot have such opposite qualities at one and the same moment.

At sunrise the real sun is still actually below the horizon, although we 'see' a red sun in the eastern portion of the

sky. The sun, therefore, *is not there at all* where we see it. This phenomenon is due to the refraction of the sun's rays. What we actually see, then, is not the sun as an *object*; it is a consciously apprehended *retinal image*, produced by the radiant energy of the sun in the organ of sight, and that is subjective.

The *stars* in the heavens present a somewhat similar phenomenon. The stars, even those which are called 'fixed,' move at tremendous speeds. We cannot see a star until the light rays emitted by it reach the eye. Light travels at a velocity of over 186,000 miles a second; despite this speed, many stars are so distant that it takes hundreds and thousands of years for their light to reach the earth. Let us assume that a certain star is a thousand light-years away and that it travels in the general direction of west to east at a rate of 1,000,000 miles a year. At the moment, then, when we look at this star, we see it where it was located *one thousand years ago*; this means, that we see it one billion miles to the west of where it is at present. The star is not there where we see it, and where it actually is we do not see it at all. And this is true of all the so-called fixed stars. We even see the sun only where it was eight minutes ago. It follows, then, that we never see the stars themselves as *real objects* in the heavens, because they are never visible as such where they actually stand. Then what do we perceive? Evidently, a consciously apprehended retinal image.

Rainbows are also phenomena which show that colors are not in the objects, contrary to the seemingly evident testimony of our eyes. The colors of a rainbow seem as objectively real in the mist or in the rain as the colors of

flowers or of other objects. Yet the water drops in which the rainbow is seen to exist are colorless. It is all a matter of the refraction and reflection of light rays. That the water drops are in no way actually colored by the light rays, is obvious from the fact that persons not standing at the proper angle will see no rainbow. A dozen persons may view a spray of water, but only a few, those who stand in the right relation to sun and spray, will see the colors; all others will see only a colorless spray. If the colors were objectively present, independent of, and antecedent to, the perceivers, all should be able to see the colored water. The water drops are thus observed to be colored and not colored at the same time, if rigid perceptionism were correct. The same is true of *mirages* and of the *iridescence* seen in oil films, soap bubbles, sea shells, and in the feathers of many birds. Aristotle and many of the older scholastics knew these facts and on their account made the distinction between 'real' and 'apparent' colors.²

The phenomena of the rising and setting sun and of the distant stars show that we do not perceive these objects themselves in any form of direct perception; and the rainbows and similar phenomena show that their colors are not in the objects. The images of these things, then, can only be *retinal images*; and they are subjective. Nor can we say that the colors are in the air or ether occupying the space between the object and the eye. Air and ether are colorless in this intervening space. If we stand at right angles to the colored object and gaze straight through the intervening space, we perceive no color traveling from the

object to the eye. Where, then, is formal color? Solely in the perceiving organ.

SIGHT: COLOR MIXTURE

There is no 'objective' *white* color in sunlight, although we perceive it frequently. The seven prismatic colors of sunlight, striking the same retinal points of the eye, produce the sensation of white, although there is no 'white' in the spectrum. In fact, all complementary colors do this, as red and green-blue, orange and blue, gold and blue, yellow and indigo-blue, green, yellow and violet. The law of color mixture reads: "For every long wave of the visible spectrum (that is, for every wave not shorter than 563.6 millimicra) a definite short wave can be found so that when the two waves are mixed in appropriate proportions, each component of the mixture will neutralize the chromatic effect of the other and the sensation of *neutral white* will arise; but if the relative strength of the two components is not appropriately adjusted, the neutralization of one component is incomplete and the result of such a mixture is the sensation of an unsaturated color whose tone is determined by that of the stronger component." This law is proved experimentally by means of the *color top or color disk* revolving at rapid speed. The disk or top still retains its original colors; but as the speed is increased the eye perceives a neutral gray. If I take one disk with 170o yellow and 190o indigo and another disk with 300o black and 60o white and revolve them with sufficient speed, both disks will look *exactly alike* in color. The eye sees the same color,

though the disks and their colors have not changed. As it is, the eye sees a color which is *not there* and does *not* perceive the colors which are there. Snow, steam, foam, and clouds appear as white, but they all consist of colorless water particles. The mass of their surfaces simply reflect *all* the colors of sunlight to the eye, and the sensation of 'white' is produced on the retina.

The *contrast box*³ makes colors appear very different to the eye than they (supposedly) are in reality. A colored background is seen through a compartment, and the latter is illuminated with different intensities of filtered lights. Without changing the background in any way, so that its 'objective' color remains the same, yellow can be made to look like an orange-red or a green; bluish-green, like a slightly greenish black; white, like a purplish red or a bluish green or a blue or a gold or even a black. We have here a case of the same color appearing to the eye as a *different* color, and each individual color can, under controlled conditions, be made to look like practically every other color.

If blue and yellow *dry powders* are mixed, the mixture appears as green to the eye, although this gross mixture does not change the original colors in any way. That the powders are still blue and yellow, can be shown by looking at the mixture through a powerful magnifying glass; the blue and yellow particles will be seen to lie in juxtaposition. Where, then, is the green color? Not in the objects, for they remain blue and yellow. Printers make use of this principle in *three-color printing*; red, blue, and yellow, by means of a mere superposition and juxtaposition of colored particles,

give the impression of all colors, although there are no intermediate colors present. The light rays, striking the same retinal elements, produce therein a sensation of colors which are blends of the original color particles. *Filtered light* shows the same effect. Take two pieces of glass, one blue and one yellow, and hold them in such a way that they overlap, but with a space between them. You, looking at the overlapped pieces, see them now as green; but others, viewing them from the side, still see them as blue and yellow. The 'objective' color cannot be blue and yellow and also green at the same time. There is no green in the glass, because the glass did not change; still, that is what you observe. Due to the difference of position, the same objects produce the impression of different colors in the eyes of the observers. And so it is with all other colors. If color were 'objective,' independent of, and antecedent to, the act of perception, we are forced to state that this objective color is 'green' and 'not-green,' 'blue and yellow' and 'not-blue and not-yellow' at the same time.

Stereoscopic color vision shows plainly that the blending of colors takes place in the organ of perception. Fasten a piece of bright blue paper over the one picture of a stereoscope and a bright yellow paper over the other; adjust the distance to the eyes in such a manner that only blue light reaches the one eye and yellow light the other eye. Here, then, we have no blending of colors in the object and no blending of light rays between the papers and the eyes. Gazing fixedly and with equal intensity at both pieces of paper (provided both eyes are practically normal in visual strength), the perception of green will gradually

appear. This is due to the chiasma, or crossing, of the optic nerve bundles of both eyes to the optic centers in the two hemispheres of the brain. This is an instance of *psychological color mixing*, and it may be considered a crucial experiment: the new color, green, is neither a blend in the object, nor in the intervening medium, nor in the single eyes, but is an effect produced by the light rays in the entire perceptive organ of sight, and it is subjective in character. Since the same principle applies to other colors, color as such cannot be objective.

SIGHT: SCOTOPIC AND PHOTOPIC VISION

There are two kinds of receptors in the retina, *rods and cones*, forming a double apparatus of sight. Physiologists have determined that the cones are the organ of high intensity or *photopic* vision, while the rods are the organ of low intensity or *scotopic* vision. The cones are adapted for brightness and the rods for twilight and darkness. The central portion of the human retina is covered with cones, and here direct vision and color perception take place; the peripheral portion of the retina is covered with rods, and here oblique vision and 'rod-white' perception occur. The cones, therefore, translate the light stimuli into colors, and the rods into 'rod-white' luminosity devoid of color. Nocturnal mammals, like mice, bats, and hedgehogs, possess no cones in their retina; they are color-blind, because color vision would be of little use to them at night. For the same reason nocturnal birds have the cones developed in much smaller quantity than diurnal birds.

Here, then, we have a double apparatus, natural and normal in every respect, designed in a most marvelous manner for functioning in brightness and in relative darkness, one for color vision and the other for neutral luminosity vision. Each operates in its own way, producing its own particular *subjective effect* in the perceiver. A simple experiment will show the double effect of the same light rays. Place three electric lamps (preferably with carbon filaments) in a row, connected together in one circuit and standing about a yard apart. Decrease the current until the filaments barely glow. Stand in such a position that only the center bulb is seen in the line of direct vision, while the two outer bulbs are seen by oblique vision only. In a darkened room the center bulb will now appear with a red glow, while the two outer bulbs will show the 'rod-white' neutral luminosity. No matter how quickly you shift your gaze from one lamp to the other, only the one directly viewed will be red; the other two will immediately change to 'rod-white.' You perceive the lamp as 'red' when its rays fall upon the cones, and as 'rod-white' when its rays enter the eyes obliquely and fall upon the rods. Although the lamps do not change color, the position of your eyes and their rod-and-cone construction produce in your retina a continuous change of color. Color, then, is subjective, dependent on the organ of perception for its existence.⁴

SIGHT: ENTOPTIC PHENOMENA

There are numerous phenomena *within the eye itself* which are impossible to explain according to the theory of

objectivity. "Thus, the 'rays' which are such characteristic features of stars, or other bright points in the visual field, are attributable not to the physical luminaries, but to the striated structures of the eye lenses. Halos, surrounding such bright points, are due to the scattering or diffraction of light by cells in the cornea. The '*muscae volitantes*,' which may move across a white paper or open sky area, are representations of tissue fragments floating between the vitreous humor and the retina. Darting and sparkling points, seen against bright backgrounds, correspond with the blood corpuscles which pulse through the retinal capillaries. Under violet illumination, the complex branching formation of the retinal blood vessels become clearly visible. These and many other 'entoptic phenomena' demonstrate that changes in ray patterns within the eye can bring about corresponding modifications of consciousness. Such facts strengthen our belief that the consciousness is adequately determined by the retinal images, without references to preceding stages of the response.

"Certain phenomena of binocular vision also contribute to this conviction. If one of the eyes is pressed out of its normal position, the visual pattern in experience is doubled. A similar effect is noticeable in the case of objects upon which the eyes do not properly converge. In these instances, the stimulus conditions external to the eyes are essentially unmodified, but the normal interrelations of the two retinal images are disturbed."

In cases of retinal detachment, the visual objects in experience are correspondingly distorted; and may even be

doubled or tripled where the receptor layer is folded over upon itself. However, we can go further than this and show that the excitation of the retina, by means other than light, yields corresponding results in the visual-experience field. Thus, pressure produces patches of brilliance, electrical currents yield color patterns, and an alternating magnetic field generates a luminous haze.”⁵

When absolutely all light is excluded from the eyes, as in a totally dark room, the resulting sensation is not that of an ideal black, but of a deep gray. This is sometimes called *idio-retinal light*, produced by the self-activity of the retinal elements.⁶

After-images also show the subjectivity of visual perception. If we keep our eyes fixed on a colored object placed on a black ground, we will notice after a time that the color gradually loses something of its luster. Then, if the eye is suddenly shifted to a white surface, we see an image of the same shape and form with the original object, but of a color complementary to the other. An original red object will thus appear as a green image, and *vice versa*; yellow will appear as violet and blue as orange, and *vice versa*. The same effect can be produced, if the eyes, after viewing the object for a time, are closed and a handkerchief or other opaque thing is pressed tight against the eyes, so as to shut out all light. In this *total darkness and within the closed eyes* an after-image of the original object will appear in perfect outline and colored with the complementary color. If, in the above experiment, the eyes are kept closed, but the handkerchief be taken away, so that light can shine through the lids, this image immediately changes into an

accidental image of the reverse color. Thus, a bright window in daylight will have dark sashes and light panes, when all light is excluded from the eyes; they will appear as light sashes and dark panes, when light is allowed to enter the eyes through the tissues of the eyelids. This phenomenon brings out a very important fact. The *change of color* here takes place absolutely *within the closed eyes*. Where, then, is this color which is so vividly perceived? Not in any object, but in the eye itself. But if *this* color is subjective, the *original* color must be in the eye as subjective also. Any other explanation would mean playing fast and loose with the facts. The 'cause' of the color is assuredly external and objective; but the 'effect' (the formal color) is internal and subjective.

SIGHT: IMAGE PROJECTION AND PERSPECTIVE

Image projection is another fact which proves that vision is subjective. To say that visual images are projected or 'externalized' seems opposed to all experience; it is apparently evident that we behold distant objects at a *distance*. However, consider the implications of the following experiment. While in a dark room, hold a burning taper about two inches away from one eye, a little in front and at the side, so as to insure oblique vision. Keeping the other eye closed, the field of vision will gradually become red. If the taper is moved slowly up and down, while the eye gazes steadily at the wall opposite, an arborescent figure of a dark color on a red field will appear on the wall. This is

the 'choroid figure,' a shadow picture of the retinal arteries and veins upon the seat of vision.

Apparently, this choroid figure is on the wall, and we do not seem to perceive it as present in the eye, although that is the only place where it exists and can be perceived to be. There is no 'objective' red on the wall, nor an arborescent figure; both are 'subjective' perception images within the eye. Is there, then, a process of real 'externalization' or projection? Evidently not; the perception takes place within the eye and stays there. Then how can the red field and the shadow figure be perceived as 'external' on the external wall? Because the perception of the wall itself is not external but internal. In fact, all visual perception is but *retinal imaging consciously apprehended as present*.

The same explanation accounts for perception of objects in *perspective*. Parallel tracks seem to converge; highways vanish to a point in the distance; all objects appear proportionately smaller the farther they are away; a near object looks larger than a distant object of the same size. If we accept the view that we perceive a consciously apprehended retinal image, everything is explained, because light must naturally strike the retinal field according to the angles and laws of perspective. This will also explain the apparent shifting of the countryside when we ride in a car or train or airplane, and the apparent position of the stars in a place where they no longer exist. All of which shows that we do not see the objects themselves; visual perception consists in consciously apprehended retinal imaging.

Such, then, is the case of *critical presentative realism*. If these facts force us to the conclusion that the secondary qualities are subjective in character and not objectively present in nature, independent of, and antecedent to, the act of perception, then rigid perceptionism must be abandoned and critical perceptionism accepted. Whether the facts as presented are convincing, is a matter for the individual to decide.

IS CRITICAL PERCEPTIONISM DISGUISED IDEALISM?

Rigid perceptionists claim that this theory destroys the truth-value of all sense-perception; it is a compromise between idealism and realism and as such has the difficulties of both without the merits of either. They are convinced that critical perceptionism must be a wrong theory, because it is against the *natural evidence of the senses*; the senses tell us plainly that secondary qualities are 'objective.' The answer to this objection is simple. The senses tell us nothing about the objectivity or subjectivity of the secondary qualities; they merely *report the presence of these qualities in our perception*. The senses cannot judge about objects and qualities. It is the *intellect alone* which interprets the data furnished by the senses and gives us a reasoned certitude as to whether these things are internal or external, subjective or objective. If rigid realists are convinced of the objectivity of all qualities, they obtain this conviction through *reason*, not through the mere sense presentation of the organs of perception. Hence, if reason

comes to the conclusion that the secondary qualities are not objective, it does not go contrary to the testimony of the senses, provided the senses themselves furnish the facts which warrant this conclusion.

Rigid realists claim that critical perceptionism leads to *idealism*: if the secondary qualities are subjective, then the primary qualities must also be considered subjective, because we would never be able to know which particular causes produce the particular secondary qualities as effects. Critical perceptionists answer that the matter is not so desperate as this. The intellect has a very simple way of discovering which bodies are the particular causes of particular effects in our sense organs. This way: My body is an integral part of my Ego; I am identified with it, and I perceive it is 'mine.' It is an extended reality, possessing triple dimensions; it possesses extended parts and members, and these I also perceive as mine. This is evidenced by my immediate consciousness, and I cannot doubt this testimony. All this was brought out in proving the real existence of extra-mental reality. Independent of all sight perception, through the *direct contact* of my body with 'other' bodies, it was proved that extended bodies, other than my own, also exist. If my body is real, they are real; if they are not real, mine is not real. I do not need sight or color or sound to prove the real existence and the real extension of extra-Ego bodies. Hence, even if all sight-perceptions be shown to be subjective, I would still have a *reasoned certitude* of extension and extended bodies other than my own, through the *direct and immediate contact* of my own body.

From this to the localization of the causes of the secondary qualities of color, sound, flavor, odor, and temperature, is an easy step. I see a lamp and touch it; I turn on the light with my hand, and it burns; I extinguish the light, and it is dark. It is clear to me that the lamp is the 'cause' of the sensation of light. I see a colored apple; I place my hand over it, and the color is gone; I remove my hand, and the color appears again. My intellect rightly concludes that this particular object, the apple, produced the sensation of color in me. I put a piece of candy in my mouth, and the taste is sweet; I hold a rose to my nose, and the odor is pleasant. If I remove them, the sensation ceases. I hold a bell in my hand, shake it, and I hear a sound; I stop it, and I no longer hear the tone. All this happens as often as I repeat the procedure. I thus know with certitude just what *particular bodies* are the *particular causes* of the secondary qualities which I perceive. Nothing more is needed for the intellect for its causal knowledge of the bodies and of the secondary sense-qualities. Rigid realists, therefore, are wrong when they assert that the denial of the objectivity of these secondary qualities would destroy our certainty of the existence of the external world. Idealism does not follow from critical perceptionism.

AGAIN, RIGID PERCEPTIONISTS CLAIM THAT MAN EXPERIENCES A *natural compulsion* in considering the secondary qualities to be objective; if they are subjective, man must be said to suffer from an *unavoidable illusion*. Critical perceptionists admit that, if there were a *real* mental compulsion here, the

question would be settled in favor of the objectivity of the secondary qualities. Such, however, is not the case; it is only an *apparent* mental compulsion. A real mental compulsion exists in analytical judgments like ' $2 + 2 = 4$ '; or in a principle which states that 'everything must have a sufficient reason for its existence and being'; also in facts perceived in a direct act of consciousness, like the fact that I am writing at this very moment. We cannot doubt the immediate evidence of our reason or of consciousness; to do so would destroy the essential reliability of our powers of knowledge. But when things are *not self-evident*, one cannot speak of a 'necessary' compulsion of our intellectual judgment.

The rigid realists themselves admit that the intellect can and does commit *errors*, in its judgment concerning the objectivity of some qualities. They lay down certain rules and conditions which the intellect must follow in order to guard itself against rash judgments and errors. But this shows plainly that the objectivity of secondary qualities is *not self-evident*; consequently there can be no necessary compulsion on the part of the intellect to judge these qualities to be objective. At best there may be an *apparent* mental compulsion; in that case, though, even a prolonged misjudgment on the part of unreflecting mankind will not justify the conclusion that a revision of our judgment would imply necessary illusion in normal perception. We see this clearly in the case of the judgment of mankind regarding the apparent movement of the sun around the earth. It is only in the last few hundred years that people have realized that the earth moves and not the sun. This revision of our

judgment was due to *science*; our eyes still see no difference between the movement of the sun and the 'noon. But if science can correct an erroneous judgment prevalent from the dawn of the human race without destroying the validity of sense-perception and of human knowledge in this case, there is no reason why it cannot do the same with regard to the objectivity of secondary qualities. Here, too, we have merely an *apparent* mental compulsion of our intellectual judgment. Critical perceptionism, therefore, does not lead to idealism nor does it destroy the essential validity of sense-perception.

This concludes our investigation into the validity of our sense-perception. It has been necessary to wind our way cautiously and laboriously, step by step, through the maze of modern errors back to the common-sense view of *presentative realism*. This we have done. First, it was imperative to expose the fallacy of idealism. Then, we had to establish the existence of extra-mental reality in our own body. Next, the existence of the extra-Ego world of material bodies had to be proved. Further, the pseudo-realism of representationism demanded refutation. Finally, we arrived at the age-old aristotelian-scholastic doctrine of presentative realism; a theory which should never have been abandoned for the excessive dualism of Descartes. It was a very roundabout detour we were forced to make in order to arrive at the solution of this perplexing problem. But the result has vindicated the *spontaneous conviction* of mankind in the reality of the world, and a truth of the greatest epistemological value, namely the *essential validity*

of sense-perception, has been critically proved and philosophically justified.

SUMMARY OF CHAPTER XII

In the question of the objectivity or subjectivity of sense-qualities, we must bear in mind that the facts must dictate the theory.

1. *The Problem of Secondary Qualities.* Rigid and critical perceptionists agree that the *primary* qualities are objective. The former claim that the *secondary* qualities are also objective, while the latter claim that they are subjective. By 'objective' rigid perceptionists mean that these qualities are present in nature, independent of, and antecedent to, the act of perception.

By 'subjective' critical perceptionists mean that these qualities are present neither in the objects nor in the intervening medium, independent of, and antecedent to, the act of perception; they are 'causally' and 'potentially' in the objects, but 'formally' and 'actually' in the perceiver.

2. *Touch, Taste, Smell, Hearing.* 'Hot' and 'cold' are relative to the perceiver's body temperature; temperature does not increase with altitude in the direction of the sun. If flavors and odors were objective, all men and animals should taste and smell these qualities in the same way; these qualities change for the same persons. Sound changes with the relative position of the perceiving ears; if sound were objective, all should hear the same tone without change.

3. *Sight.*

Refraction of Light. Due to refraction, we perceive the sun before it is above the horizon; the sun also appears to change in size, shape, and color, although the sun does not change. Stars are seen, although they are not present where perceived to be. Rainbows are observed in water drops; but the water is really colorless. The same applies to mirages and iridescence.

Color Mixture. White sunlight is not objective. The colors of a color top remain unchanged, but they change for the eye. The contrast box makes colors appear as different. Pigments and filtered lights show blends of color which are not objective. Stereoscopic color vision reveals psychological color mixing which under no circumstances is objective.

Scotopic and Photopic Vision. The rods and cones are a double apparatus of sight; the cones translate light rays into color vision and the rods into neutral luminosity vision. The effects, of course, are subjective.

Entoptic Phenomena. Many phenomena occur within the eye which are apparently objective. After-images can be seen with closed eyes.

Image Projection and Perspective. The choroid figure appears as if projected and externalized, although it is obviously Only an intra-ocular perception. Perspective vision also shows that vision is consciously apprehended retinal imaging.

4. *Disguised Idealism?* Critical perceptionism is not contrary to the natural evidence of the senses: the senses merely report the qualities; it is the intellect which must interpret the data furnished by the senses. It does not endanger the objectivity of the primary qualities, because the extended character of our bodies enables us to know which objects are the causes of our visual perceptions. There is no unavoidable illusion in critical perceptionism due to natural mental compulsion: the facts of perception are the reason why the secondary qualities are considered to be subjective.

The *essential validity* of sense-perception is vindicated and critically established.

Chapter 13

THE PROBLEM OF THE UNIVERSALS

SECTION II - INTELECTION: IDEAS, JUDGMENTS, REASONING

SO FAR WE HAVE ESTABLISHED THE VALIDITY OF CONSCIOUSNESS and of sense-perception as a source of human knowledge. Our consciousness acquaints us with the various mental states which occur within our own self as 'subjective events,' such as thinking, willing, imagining, striving, emotion, sensation. Sense-perception brings our own body and the external world within the field of knowledge, so that we obtain a cognition of them as 'objective events' through the medium of our sense-organs. But we also have an *intellectual knowledge* of things, and this knowledge manifests itself in ideas, judgments, and reasoning. It will now be our task to examine the validity of our intellectual knowledge.

Our reasoning processes consist of judgments, and these processes cannot be valid, if our judgments are not valid. Judgments, on their part, consist of ideas, and hence cannot be valid, if our ideas are not valid. It will, then, be necessary first of all to submit our *ideas* to a critical investigation of their essential validity before we pass on to the validity of our judgments and then to that of our reasoning.

THE PROBLEM OF THE UNIVERSALS

There is a close connection between the intellect and sense, between intellectual knowledge and sense-knowledge. The proper object of our cognition is the *sensible*. Our senses contact the external world by means of a cognitional image

through which the material, external objects are *perceived*. Thereby the objects become 'present to sense' and also 'present to consciousness,' and they are thus sensuously 'known.' This process is the same for men and brutes, because they are sentient beings.

Man, however, is also an *intellectual* being, and as such has a form of knowledge distinct from sense-perception: man *thinks*. In the presence of this 'percept,' the mind forms a concept.' Since sense and intellect are both faculties of the one, identical Ego, the intellect fashions a 'concept' or 'idea' of the external object perceived by the sense. The intellect now is aware of the existence of the object, and so the object becomes present to sense' and also 'present to intellect' at the same time. It is really the *Ego* that is the active agent of 'perceiving' and 'conceiving' and that forms within itself the 'percept' of sense and the 'concept' of intellect. Our consciousness testifies to this very plainly: I see the thing, I have an idea of the thing. And our experience tells us that our Ego forms the concept of a thing in the intellect after it has had the percept of it in the sense: we first 'perceive' the thing, and then 'conceives it by means of a concept or idea. In other words, our knowledge begins in the senses and ends in the intellect. Intellectual knowledge presupposes sense-knowledge. The materials for our ideas are drawn from the percepts of sense, so that we could have no intellectual knowledge of things, if we did not have sense- knowledge first. Hence the principle: '***Nihil est in intellectu quod prius non fuerit in sensu***; nothing is in the intellect which was not beforehand (in some manner) in the sense.

Sense and intellect, percept and concept, are thus seen to exist in close relationship. Nevertheless, there is a great difference between percept and concept, between sense-knowledge and intellectual knowledge. Both sense and intellect make an 'image,' a 'representation' of the object which is present to them, but the nature of this image or representation is very dissimilar. Things in nature are always singular, individual, concrete, and the sense-image of them depicts them in their *singularity, individuality, and concreteness*, and so this image itself has a content which is singular, individual, and concrete. When the sense perceives, for instance, a man, it will always be a definite man in all his individual characteristics, such as size, shape, color, age, sex, weight, and mannerisms. Not so the intellect. It apprehends that which pertains to man as man. The *intellectual image* retains only that which all men have in common, that which makes a man to be what he is precisely as a member of the *class* of men, leaving aside all those characteristics which distinguish one man from another, like size, shape, color, age, sex, weight, and mannerisms. Instead of depicting the exterior elements, as the sense-image does, the intellectual image represents the elements which constitute the nature of man: man is conceived as a 'rational, sentient, living, corporeal substance.' This idea now fits every single man and all men as a class; it applies to them individually and collectively. To drop the individualizing properties of a thing in this way and retain the elements common to the class is the process of intellectual 'abstraction.' Intellectual images are,

therefore, not singular, individual, and concrete, but *universal, general, and abstract*.¹

In actual sense-perception we have a singular, concrete sense-image which applies only to a single, concrete man; each image is different according to the individual differences existing between the single persons; and each image is restricted according to time and place, depending upon the conditions of time and place prevailing for the individuals perceived. This is not the case with the intellectual image or idea of a man. It is *one* in content, but it applies to *all* men, living and dead, actual and possible; all the individual differences between individual men are eliminated, and the *common element* is represented and expressed; temporal and spatial conditions are absent in the idea, so that it has value for all times and in all places. The idea of 'man' as a 'rational, sentient, living, corporeal substance,' since it is an abstract and universal image of the elements common to all men, contains those elements of man which are *fixed, unchangeable, necessary*: these elements are such that they cannot be missing without man ceasing to be man, because they constitute that which makes him to be what he is a 'man,' and these elements must be and will be found in all men at all times and in all places.

What has just been said is true of all concepts or ideas: they are *abstract and universal*. We have taken the example of 'man,' because it is fairly obvious; any other object will show these characteristics of the idea just as well. Our idea of a 'plant' as a 'non-sentient, living, corporeal substance' applies to the rose, the pumpkin, the elm, the pine, the

chrysanthemum, and to every other plant with equal truth. Our idea of a 'building' fits the home, the business office, the school, the shack, and any other building. Our idea of a 'dog' applies to the mastiff, the bulldog, the greyhound, the poodle, and all other dogs. And so with all other ideas. They apply to every single individual belonging to the class and to the class as a whole. And that is what is meant by a *universal idea*: one that represents some common nature or attribute which can be applied to a *class as a whole* and to *each individual* of that class.

This brings up the question of the *validity of ideas*. Since ideas are abstract, leaving aside all individualizing factors and retaining an attribute or nature common to one and many, they are *universal*. But therein lies a problem. Ideas are supposed to be representations of things as they are in themselves; then universal ideas must also represent things as they are in themselves. But how can they? A universal idea is one whose thought-content (comprehension) applies to a class as a whole and to each and every member belonging to that class. The idea 'man,' for instance, applies in the same way to 'each man' taken singly and to 'all men' taken together as a class. If this universal idea is a true representation of man as he is in reality, it would seem to imply that 'man,' as found in reality, has a nature which is 'single' in each individual and also one in the whole class. The nature of 'man' would be *one* because it applies to the class as a whole; and it would be *multiple*, because it applies to each individual of the class. How can it be *one and multiple* at the same time? It would seem that, if it is one, it could not be multiple; and if it is multiple, it could not

be one. Does this not make our universals essentially invalid? Or how can we reconcile this apparent contradiction in the very nature of the universal ideas? The problem of the universals can be formulated in the question: *How can or do the universals apply validly to things*, so as to give us a genuine knowledge of reality?

IMPORTANCE OF THE PROBLEM

At first sight it might appear that the problem is of trifling significance. But this is not so. If our universal ideas do not give us a true representation of reality, the whole fabric of our *intellectual knowledge is destroyed*. Universal ideas form the warp and woof of this fabric; if they are false representations of reality, our entire intellectual interpretation of reality is false. The judgment is supposed to interpret reality in such a way that the truth of the judgment is a similitude of the truth of the reality expressed in the judgment. If our universal ideas are false, our knowledge of reality is false. Then what becomes of the validity of our intellect and its knowledge? Once we come to the fatal conclusion that our intellect is not a valid source of truth, we have demolished the very foundation of *reason* and of our *reasoning processes*; our reason must be adjudged untrustworthy in its operations and its findings fallacious. Such a conclusion would not only be intellectual suicide for the individual person, but would undermine the very structure of human society in its moral, commercial, economic, political, and international associations. The validity of our intellectual knowledge must be maintained

and vindicated, if man is to live as a human being and not be degraded to the sense-level of the brute.

Then, too, if the validity of our intellectual ideas cannot be upheld, *science* is a chimera. It is not the purpose of science to state individual facts and record individual events. It is of no interest to science to know that 'this particular glass of water has a temperature of 56°; 'this man is white'; 'this plant is ten feet tall'; and so forth. These are individual facts of no importance. What the sciences really attempt to discover are *general truths, permanent facts, necessary relations, universal laws*, which are not only true and valid now and then, here and there, but *always and everywhere*, independent of the individual circumstances and conditions. Such truths, facts, relations, and laws are of incalculable value for mankind in general, since they are the steppingstones of material and intellectual progress. Destroy the validity of these and humanity is poor indeed, because its highest form of knowledge, that of the intellect, is essentially false and unreliable.

Science deals with the *universal*. The basic ideas underlying all scientific thought and investigation are universal. 'Substance, accident, quality, quantity, action, reaction, force, energy, cause, effect, law, principle, condition, experiment, variation, uniformity,' and a host of similar ideas, are all universal ideas. Take these ideas and their validity out of science and it vanishes into nothing. Such ideas are essential to all sciences, and without them the sciences lose all meaning and value. Remove the

universal ideas from the pages of scientific books and nothing but the covers would be left.

The same is true of the *scientific laws* formulated by science as the result of its inductive research into the phenomena of nature. These laws can never be expressed in language except with the aid of universal ideas. Consider, for example, Ohm's law: 'The currents furnished by different galvanic cells, or combinations of cells, are always directly proportional to the electromotive forces existing in the circuits in which the currents flow, and inversely proportional to the total resistances of these circuits.' Here again the essential ideas of the law are universals: 'current,' 'cell,' 'combination,' 'force,' 'circuit,' 'resistance.' Or, take the formula of the index of refraction: 'The ratio of the speed of light in air to its speed in any other medium is called the index of refraction of that medium.' 'Ratio,' 'speed,' 'light,' 'air,' 'medium,' 'index,' 'refraction' – these are all universal ideas. We thus see that the laws of science are expressed by means of universals.

Now, the sciences are supposed to be a true representation of *reality*. If they fail in this, they are useless as a source of knowledge. But they cannot be a true representation of reality, unless the universal ideas, which they constantly employ, themselves *represent reality* in a valid manner. The sciences, then, stand and fall with the universals. The problem of the universals, therefore, is not an idle speculation of idle minds, as many scientists and philosophers have asserted, but a vital issue involving the very existence and validity of science itself.

This brings us again to the question: Is there a *reality in nature* which corresponds to our universal idea? If so, how can our universal idea be a correct representation of this reality, considering the fact that it expresses a common nature or attribute which can be applied to a *class as a whole* and *to each individual* of that class? Since the universal has a thought-content which is one-in-many, does this mean that the reality represented by it is also 'one-in-many,' so that all members of a class share in a single nature or attribute common to them all together? And if this is not the case, can the universal be said to interpret reality correctly? How can we harmonize the *individual things* with the *common* essence expressed in the universal idea?

The problem is not simple. On the one hand, we have the apparently obvious fact that the things in the world are *individuals* and possess a single essence of their own. Every individual is a distinct being in itself, having a nature which is not shared by any other being; there are, then, as many distinct natures as there are individuals in existence. There may be two billion men on the globe; but each man is an individual human being in his own right, complete in every respect in his nature, so that we have two billion distinct human natures existing as separate realities, and not merely one single human nature shared by the two billion men in common. This *singularity* of the individual must be upheld. On the other hand, our universal idea is conceived as something which represents a nature or attribute which is one in the individual and yet *common to all* as a class. This would seem to be in contradiction to reality as just

pointed out. The world consists of 'individuals,' not of 'universal essences.' But if there are not 'universal essences' in the world, common to all the members of a class, the universal idea seems manifestly false. And yet, we must maintain the essential validity of the universal idea, otherwise we will undermine the foundations of our intellectual knowledge and of the sciences. How can we reconcile the seeming antinomy between reality and the universal idea?

HISTORY OF THE PROBLEM

The problem of the universals has vexed the minds of thinkers from the beginning of philosophy in Greece up to the present time. *Plato* (427 or 428 to about 348 B.C.) brought the problem into prominence by his doctrine of the *Ideas*. *Socrates* (469—399 B.C.) had taught that the 'concept' of a thing is necessary in order to know the reality of a thing. *Plato* concluded that the 'concept' or Idea is the only reality which is permanent and unchangeable in the continuous flux of concrete phenomena. The Idea is thus the very essence of the reality of 'being' and of the reality of scientific 'knowledge.' The ideas are, therefore, not only *objects of thought*, but also *realities in themselves*; they not only exist as universals in the mind, but also as universals in *nature*. Subjectively and objectively they are truly universal. The concepts of our intellect are universal, because they represent the universal Ideas which exist independently of the mind in a world of their own. The Ideas are real things, beings, essences, which subsist entirely outside the physical

world of concrete phenomena which we see around us, in a *transcendental world* of their own, in a heavenly sphere of unchangeable existence, where they have an eternal being.

The physical objects of the material universe are nothing but faint copies of these eternal Ideas, and such objects, since they are singular in essence and in a continual state of change, cannot account for the permanent and universal concepts in our minds; our universal concepts, and the scientific knowledge based on them, can derive their origin only from the eternal and universal Ideas. Man, therefore, must have had a *previous* existence in which he possessed a direct intuition of these Ideas, and his present universal concepts are but the products of a *reminiscence* of his former contemplation of these Ideas in the transcendental realm. There are, then, three distinct worlds for Plato: the world of absolute and eternal Ideas, the world of concrete, ever-changing phenomena (the universe), and the world of universal concepts in our mind. For every single universal concept in our mind there exists a corresponding universal Idea which has its own being in this noumenal world, because our concepts are merely intellectual copies or reproductions of them. These Ideas are *the original* universals, prior in existence to the physical world and to our universal concepts. Our universal concepts are valid, therefore, because they are a faithful representation of reality, namely of the reality of the Ideas which are themselves universal and eternal. By means of this unique theory Plato attempted to show that our universal concepts or ideas have objective value and can give us true scientific knowledge.

Aristotle (384—322 B.C.) realized that Plato's theory was without any basis in fact and that his 'world of Ideas' was pure fiction. The problem would have to be solved without the aid of such a fanciful dreamland of isolated Ideas, because it removed the universals completely from the sense-world to which they are supposed to apply. The reality to which our universal ideas correspond must be present in the things of the sense-world in *some manner*. Plato maintained that our intellect first acquires a knowledge of the Ideas and from them acquires a knowledge of the individual objects in nature; Aristotle reversed the process, claiming that we form our universal ideas from the *sense-impressions* of the external phenomena. Plato considered the Ideas as possessing an existence independent of the sense-world; Aristotle denied such a separate world of Ideas and placed the objective content of our universal concepts in the individual objects existing in nature. Plato attributed a formal universality to the Ideas in their very being; Aristotle taught that there is no universality of being in nature but only individual essences, and the 'universality' of the universal is merely a *logical mode* of our concepts existing *in the mind alone*. In other words, the universal *as a universal* exists only in the mind; the things themselves, of which our concepts are a representation and which the mind universalizes, are individual beings.

Each individual being has its own individual essence, endowed with numerous properties and attributes not found in the others in the same way, so that it is numerically single and separate; but each individual of a certain class or

type possesses an essence which is *similar* to that of every other member of that class or type with the similarity of a perfect likeness, so that the intellect grasps this perfectly similar essence, leaving the individualizing characteristics aside, and *universalizes* it in a single idea. The intellect considers this similar essence as being 'one-in-many,' as being a common class-nature, although it realizes that in reality itself these essences are all individual and distinct. The foundation for this universality of the universal idea is thus seen to consist in the perfect *similarity* of the essences, after they have been divested of the individualizing differences existing between them. This mental process of 'universalizing' the individual essences is, then, not an arbitrary process of the mind, but is grounded in the similarity of these individual essences themselves; being similar, they are expressed in a universal idea. The content of the universal idea is real in nature, because it represents the reality of each individual essence; but the universality of the universal idea is mental, because the individual essence is itself not universal in nature. While Plato advocated an *extreme realism*, Aristotle proposed a *moderate realism*, thereby safeguarding both the validity of the universal idea and the reality of the individual essences.

The problem now rested until the beginning of medieval philosophy. Except for a few sections, the writings of Plato and Aristotle were unknown to Western Europe, having been lost in the disintegration and downfall of the Roman Empire. A passage in the *Isagoge of Porphyry* (233—304), the Neo-Platonist, aroused the interest of medieval thinkers concerning the universal ideas and the reality

corresponding to them. Porphyry proposed a *triple problem*: Do the generic and specific concepts (universals) exist in the real world, or are they mere products of the intellect? If they are extra-mentally real, are they corporeal or incorporeal things? Are they realized in the concrete individuals of the sense-world or outside and separate from them?² It was the first of these questions of Porphyry which the early medieval philosophers tried to answer. Once the question was raised, a controversy ensued which lasted three hundred years before a conclusive answer was found.

From the very outset the tendency of thought was toward *extreme realism*, but it was not always toward the Platonic type. The Ideas of Plato were universal realities which existed in a separate world of their own, entirely distinct from the individual essences or things in nature. *Empiric* ultra-realism placed the universal reality *in the things themselves*, in physical nature around us. All members of a class possess *one single essence* which is common to them all and in which all share equally, so that they actually have a common class-essence. The individuals no longer possess their own distinct essence, numerically different from that of the other members of the class, but all together possess a single identical essence which is strictly a *universal essence*. The difference between individuals consists merely in *accidentals*, in 'individuating notes' (*notae individuanes*), such as form, figure, place, time, ancestry, country, and name. All men, for instance, form together a single universal essence, humanity; in strict truth, there are no 'men' but only a 'universal man.' Pressed to its logical conclusion, it would lead to the

doctrine that all things and persons are a single 'universal being', since 'being' is also a universal idea; and this would be *pantheism*. If medieval empiric ultra-realists refused to take this final step, it was mainly due to their religious beliefs. *John Scotus Eriugena* (born between 800 and 815; died after 877), however, passed the boundary line and taught an undisguised pantheism. *William of Champeaux* (1070—1120), was an empiric ultra-realist, while *Bernard of Chartres* (died about 1130), *Theoderic of Chartres* (died 1155) and *William of Conches* (1080—1154) were ultra-realists of a type which resembled Plato.

Some of the advocates of modern *critical realism* are ultra-realistic in their interpretation of the 'essences' we perceive. These 'essences' are considered as 'universal,' independent of the thinking mind; they bear a close resemblance to Plato's Ideas. Another type of extreme realism is found in *monism*. According to monism, there exists but a single principle of being, constituting all things. Monism, in the strict sense, considers this principle of being as numerically one, uncreated, eternal, and real. It is frequently called the *Absolute*; whether in a pantheistic or naturalistic sense, depends upon the interpretations of the individual philosopher. Others speak of the 'absolute Ego,' 'absolute universal consciousness,' 'cosmic universal idea,' 'universal energy,' 'universal actuality,' 'universal will,' 'the unknown,' and so forth. The Absolute embraces within itself everything that exists: the ideal and the real, thought and thing, mind and matter, spirit and nature, the logical and the ontological. These things are not really distinct and different entities; they are but parts, forms, modes,

manifestations, or appearances of the Absolute; they are identified in the Absolute, and the Absolute is self-identical in them all. The Absolute undergoes an eternal and necessary *evolution* by means of a process of self-determination, which makes it assume these various forms or modes. Monism is thus opposed to *dualism*, which affirms the essential distinction between God and world, mind and matter, living and non-living beings, and to *pluralism*, which asserts that reality consists of numerous individual substances and not of one sole absolute being. *Spinoza, Fichte, Schelling, Hegel, Schopenhauer, v. Hartmann, Bradley*, and many others, were monists. In as much as the Absolute is a nature which is 'one-in-many,' it is universal; and since this universality is extra-mental, monism is a form of extreme realism.

Nominalists deny that the reality corresponding to our universal ideas is in any way universal in *nature* and even deny that our ideas themselves are universal; only the names are universal. We have collective ideas or images and give them common names, so that we merely designate or 'label' the individuals with the same name; but there are no universal ideas in the intellect which correspond to these universal names. This theory, as will be noted, is the very opposite of extreme realism. Representative medieval nominalists are *Roscelin* (born about the middle of the eleventh century, and died about 1100), *Berengar of Tours* (999—1088), *Adelard of Bath* (beginning of twelfth century), and *Walter of Mortagne* (died 1174). It is more than doubtful, however, whether these men should be classed as nominalists in the present meaning of the term

and in the sense as outlined above. Their position was *negative*; they opposed the extreme realism advocated by many of their contemporaries without making much of an attempt to give a positive solution of the problem. The phrasing of their thoughts sounded nominalistic, but they scarcely intended more than a refutation of the doctrine of extreme realism. Their views were only a tentative groping for a solution, pointing future philosophers in the right direction; they themselves were content with showing the deficiencies of ultra-realism.

Nominalism proper is the outgrowth of sensism, empiricism, and materialism, in as much as these theories assert that intellectual knowledge is only a refined sense-knowledge. Since the senses can perceive nothing but the individuals in the sense-world, our intellect can fashion ideas only of individual things; hence, our ideas are really singular, not universal. We indeed have 'general images' of a dog, of a man, of a tree, of a fish, and our so-called universal ideas express such 'general images'; but strictly 'universal' ideas which would represent a common element or attribute as one-in-many, are non-existent in the mind. They maintained a universality in the name and nothing more. This theory was upheld by *Hobbes* (1588—1679), *Locke* (1632—1704), *Berkeley* (1685—1753), *Hume* (1711—1776), *John Stuart Mill* (1806—1873), *Bain* (1818—1903), *Spencer* (1820—1903), *Huxley* (1825—1895), *Sully* (1842—1923), *Herbart* (1776-1841), *Wundt* (1832—1920), *Condillac* (1715—1780), *Comte* (1798—1857), *Taine* (1828—1893), and many others up to our present day. Since many *neo-realists* and *critical realists* are materialists,

identifying mind with brain, their theory is more or less nominalistic. While the theories propounded by these thinkers differ on many points, they all agree in considering our intellectual knowledge as nothing more than a mere piecing together of sense-images to which we give a common name or 'label.' The intellect possesses no higher power of 'abstraction,' enabling it to grasp the essences underlying the external phenomena of things and expressing them in universal ideas.

Conceptualism is another theory which developed out of the problem of the universals. It is closer to the correct solution than nominalism, but it falls short of the goal. In opposition to the nominalists, conceptualists defend the universality of ideas in the mind. Like the nominalists they deny the external reality of the universals in nature; but, unlike the nominalists, they maintain that our universal 'names' are expressions of genuinely universal 'ideas,' so that the latter actually represent to the mind an essence which is one-common-to-many. The main point in conceptualism, however, is the contention that the content of our universal ideas is *not realized* in any form whatever in the *individual sense-objects*: there is no foundation in the things themselves which would justify the intellect in forming universal ideas. Our universal ideas are thus purely subjective products of the mind without a correlative in nature in other words, there is nothing in the individuals in nature which is genuinely represented by these universal ideas. This, of course, gives to the universals only a strictly intra-mental significance; as 'universals' they have no objective value. Among the medieval philosophers it is

customary to class *Peter Abelard* (1079—1142) and *Gilbert de la Porrée* (1076—1154) as conceptualists. But here again, the defective phrasing of their thoughts and the lack of a complete understanding of the implications contained in their expressions urge historians³ to class them rather as precursors of moderate realism than defenders of conceptualism proper. The case is different with *William of Ockam* (died about 1347). The problem of the universals had already been solved in his day, and he opposed this solution with a doctrine of his own which was really conceptualistic.

Modern conceptualism is the offspring of idealism. *Kant* (1724—1804) and his followers are the protagonists of this theory. Kant actually tried to prove the validity of our universal ideas by showing that the categories of the understanding are applicable to the data of sense-intuitions; but his interpretation of the manner in which our universal ideas are formed from these intuitions of sense make them invalid as representations of reality. According to him the data of sense are united with the pure categories of the understanding. These categories, however, are *innate a priori forms* of the understanding and are in no way derived from sense-intuitions. The mind superimposes these categories upon the data of sense, and now we apprehend in these combined products of sense-data and categories relations which are ‘universal.’ We do not derive our universal ideas by means of abstraction from the sense-data themselves; the universality of the idea is exclusively the product of the intellect, without a foundation in the extra-mental reality of the things in nature. In fact, the things in

nature are noumena which are forever unknown and unknowable to us. Our universal ideas thus have no reality corresponding to them in the outside world and are mere creations of the mind; and that is the theory of conceptualism.

Pragmatists are also to a great extent conceptualists. For many of them the things of the physical world are not 'independent realities,' and we can never know reality as it is in itself; the 'category of transperceptual reality' is after all only 'an intra-experiential affair.' Our abstract concepts are looked upon as 'man-made products' and as 'artificial mental things.' Truth is relative to the individual mind, and all knowledge is valid so far as it satisfies human needs. That there can be *no objective value* to our universal ideas in such a system is obvious, *James, Schiller, Bergson, Dewey*, and their followers all subscribe to this personal 'cash-value' theory of truth and reality. This, however, is the viewpoint of conceptualism, since it robs our universal ideas of an objective foundation in outside reality.

Due to the constant friction of minds in the controversy over universals, a theory of moderate realism gradually emerged toward the end of the twelfth century which satisfied everyone as the correct solution. *John of Salisbury* (died 1180) explained the validity of the universals in its essentials according to the spirit of Aristotle. *Albert the Great* (born 1193 [or 1206, or 1207]; died 1280) formulated a complete solution along aristotelian lines. It remained, however, for *St. Thomas Aquinas* (1225—1274) to search into the problem with such penetration, clarity, and brilliance of thought that this vexing question was

considered to have received its conclusive and ultimate answer. Against *extreme realism* he maintained that the universals do not exist as 'realities' outside the mind, neither in a world of their own nor in the universe of sense-objects. If extreme realism were correct, we could not explain the 'individuality' of the physical things. Against *nominalism* he maintained that the universals are more than universal 'names'; our ideas are genuinely universal in the mind. If nominalism were correct, our intellectual knowledge would not differ from sense-knowledge. In giving his solution, he maintained that our universal ideas have more than a 'subjective value' for the mind; they are really representations of 'extra-mental reality.' He agreed with extreme realism that there must be *some objective reality* outside the mind which the universals represent; and he agreed with conceptualism that this objective reality could not consist in *universal essences* outside the mind.

Each of these other systems has an element of truth and an element of error. *Moderate realism* retains the truth and eliminates the error of all. The separate essence and existence of every individual being in nature must be upheld inviolably, because nothing exists in nature but *individuals*; this excludes all universal essences. But while nature consists of individual essences, these individuals form *natural classes*, for instance, fishes, birds, mammals, men, animals, plants, bodies, substances.

The mind apprehends that which the senses cannot perceive, namely the essence which is *not identical* (as the extreme realists claim) but *similar with a perfect likeness* in each individual of a natural class. It is because of this

perfect likeness that the intellect recognizes the individuals as belonging to a class and groups them together in a 'universal' idea. This *similarity* of the individual essences constitutes the objective reason or foundation for the *universality* of the class-idea in the mind, so that the mind is entitled to 'universalize' the individual essence. St. Thomas summed up his doctrine in the famous principle: 'Universals are *formally* (i.e., strictly, as universals) in the mind, but *fundamentally* in the things themselves.' As will be noted, this solution of the problem is in full accord with the original interpretation of Aristotle, and henceforth historians have called it the 'aristotelian-thomistic,' or moderate, realism. It is opposed to ultra-realism, nominalism, and conceptualism.

There are, then, four systems of thought which claim to give an adequate account of the universals: ultra-realism (extreme realism), nominalism, conceptualism, and moderate realism. We must now investigate them.

SUMMARY OF CHAPTER XIII

Our intellectual knowledge consists of ideas, judgments, and reasoning. In establishing their truth-value, we must begin with the validity of ideas.

1. *The Problem of the Universals.* Our intellect derives its knowledge originally from the senses: concepts follow percepts. Concepts or ideas are intellectual representations or images of things. While the sense-image is singular, individual, and concrete, *the idea is universal, general, and abstract*; it is not restricted, like the sense-image, by conditions of time and place, but is *fixed, unchangeable, and necessary* in its content. The content of the idea is 'one-in-many,' i.e., it represents some common nature or attribute which can be applied to a class as a whole and to each individual of that class.

But therein lies the problem of its validity. Since universal ideas are predicated of individuals and also represent the *class-essence*, it would seem to follow that class-essences as such must either exist in nature or that the universals do not faithfully represent reality. Either alternative involves serious difficulties.

2. *Importance of the Problem.* If our universal ideas are not a faithful representation of reality, the foundation of *reason* and of our *reasoning processes* is destroyed. *Science* is concerned with general truths, permanent facts, necessary relations, and universal laws; all this presupposes the validity of universal ideas. The value of science as a true representation of reality thus depends upon the truth-value

of the universals. But how can we harmonize the *individual* things of nature with the *necessary* and common essence expressed in the universal idea?

3. *History of the Problem.* To safeguard the necessary and universal character of scientific knowledge, *Plato* maintained that for each universal concept of the mind there exists a corresponding universal Idea as a reality in a noumenal world outside the mind and outside the physical universe. *Aristotle* claimed that the mind derives its universal ideas from the individual sense-natures, due to their similarity; he thus advocated a *moderate realism* in opposition to *Plato's extreme realism*.

Medieval *empiric ultra-realism*, in contradistinction to *Plato*, placed the universal essences in the physical world, so that all individuals of a class share in this common nature or essence this again was ultra-realism. Others disputed this, by disclaiming all universality; they were nominalists, since only the name or word was considered universal. Conceptualists, on the other hand, asserted that our ideas are truly universal, but there is nothing in the individual things to justify this 'universalization' on the part of the mind. *St. Thomas Aquinas*, following *Aristotle*, found the justification for the process of universalizing in the *similarity of nature* existing in the individuals and formulated the solution in the principle: 'Universals are formally in the mind, but fundamentally in the things themselves.'

We thus have four theories concerning the universals: ultrarealism, nominalism, conceptualism, and moderate realism.

Chapter 14

THE TRUTH-VALUE OF THE UNIVERSALS

THE VALIDITY OF OUR INTELLECTUAL KNOWLEDGE DEPENDS ON THE truth-value of the universals. The problem is based on the apparently evident principle that, when we know an object, we must know the object as it is, or our knowledge is false. If this principle is interpreted rigidly, there must exist an extra-mental universal object corresponding to our universal idea; that would mean *extreme realism*. If we deny not only the extra-mental universal object but also the existence of the universal idea in the intellect, we have *nominalism*. In order to avoid the difficulties of extreme realism and nominalism, we may reject the principle that our knowledge must correspond in every way to the object. If we deny the principle of correspondence altogether and assert that we have universal ideas, but that they are pure fictions of the mind, without any foundation whatever in the extra-mental objects, we subscribe to *conceptualism*. We may, however, accept the principle that an extra-mental object must exist with which our universal idea corresponds, but that it need not exist in the same 'manner' in which the mind knows it; this view, which accepts universal ideas in the mind, with a foundation in the extra-

mental individual objects to account for their universality in cognition, is *moderate realism*. We maintain that moderate realism alone correctly solves the problem.

CRITIQUE OF EXTREME REALISM

According to the ultra-realistic view, our universal ideas are representations of objects which are *as such* objectively, extra-mentally, *formally* universal *in themselves*. Universal ideas are supposed to have a content which is 'one-in-many,' because the objects themselves are essences which are 'one-in-many.' This theory rests on the principle that our ideas must correspond in every respect to the objects in order to be true knowledge. For this theory of extreme realism to be correct it would be necessary for the ultra-realists to prove that an *absolute* correspondence between thought and thing is required for the truth of knowledge. This, however, they cannot prove.

As a matter of fact, all knowledge is in the knower according to the nature of the knower. In sense-perception knowledge is obtained according to the character of the individual sense-organ which perceives the object, and each sense reacts in its own way to its respective stimulus. The eye, for instance, reacts to light waves, but not to sounds or flavors or odors or temperature; the ear reacts only to sound waves, but not to other stimuli; and the same is true of the other senses. No single sense conveys a complete picture of the object to the mind; nor do all the senses taken together. Furthermore, in our inquiry into the truth-value of sense-perception we have noticed that the objects

do not correspond in absolute fashion to the perceptions of them which take place in our sense-organs. The *manner* in which objects *exist* is somewhat different from the *manner* in which they are *perceived*. This is simply due to the fact that the percept is a 'vital' similitude of the object, and it must conform to the nature of the perceiver. Just as a photograph, while it does not resemble the object in every respect, is a true representation of the thing photographed, so sense-knowledge is a true, though an inadequate and incomplete, representation of the thing perceived. But if sense-knowledge is true, without the necessity of an absolute correspondence between its manner of representation and the object's manner of existence, there is no reason for demanding such an absolute correspondence between the intellectual idea and the object it represents. The intellect could thus group a number of similar individuals under the class-notion of a universal idea, although these objects do not exist as *universals* outside the mind; the manner of representation would be different from the manner of existence, but the *content* of the idea would bear a faithful resemblance to the object itself as it exists in nature. Correspondence between idea and object there must be; but it need not be a complete and absolute correspondence *in every respect*. Hence, the reason which prompted the ultra-realists to postulate the existence of universal objects or essences is seen to be erroneous.

Again, there is *no empirical evidence* whatever for the existence of universal objects or essences outside the mind; it is a pure assumption. The data neither of internal nor of

external experience reveal in any way the existence of an object or essence which could be said to be 'one-common-to-many.' Our experience tells us clearly that individual men, trees, animals, stones, metals, and similar objects, exist in nature; but nowhere do we find anything that would correspond to our idea of a universal man, or of a universal tree, or of a universal animal, or of a universal stone, or of a universal metal, and so on. The only actual things we know are single, *individual* objects, not universal natures and essences; and there is nothing in nature to indicate the existence of such universal entities. Not only do the objects in nature appear as individuals; they also *act* as such. Nothing is clearer to us 'through our experience than the fact that we are individual men in our own right; but of universal beings, for instance, of a universal man or humanity, we have no experience at all. Then why accept something for which no objective evidence can be discovered within or outside us?

After this general argument, we must turn our attention to the various types of ultra-realism.

Platonic ultra-realism leads to evident absurdities; hence, it must be false.

We must bear in mind that, according to this theory, the universal essences are *in reality* as our universal ideas are *in the intellect*; in other words, they *really exist* in the same manner as we *conceive* them. Let us see just what this means.

We possess generic universal ideas, like 'animal,' 'organism,' 'body,' 'substance.' By 'animal' we mean 'a sentient organism.' Our idea does not state whether this

sentient organism is 'rational' or 'non-rational'; the distinction is omitted, so that the definition applies to both the rational and non-rational animals, to men and brutes, but the idea of 'animal' is *conceived as being neither rational nor non-rational*. And that is precisely the way in which the Platonic Idea or essence of 'animal' must exist: it is neither rational nor non-rational, but indifferent. That, however, is impossible. The terms 'rational' and 'non-rational' are contradictory and mutually exclusive. An existent thing must be either one or the other; it cannot be both nor can it be neither. If it is 'rational,' it cannot be 'non-rational,' and if it is 'non-rational,' it cannot be 'rational'; and if it is anything at all, it must be either 'rational' or 'non-rational': otherwise the Principle of Contradiction would be violated. Since, then, the Platonic Idea or essence of 'animal' would be neither a rational nor a non-rational entity, it violates the Principle of Contradiction and is thus an absurdity. And if it is stated that this essence is both rational and non-rational, because our idea of 'animal' applies to rational men and non-rational brutes, it would again violate the Principle of Contradiction, because no entity can be both rational and non-rational at the same time. To state that the universal essence of 'animal' is 'rational' (but not 'non-rational'), would exclude all brutes from this universal essence; and that is inadmissible, because the universal idea of 'animal' in our intellect applies also to the brutes. And it would be equally inadmissible to accept this universal essence as 'non-rational' (but not 'rational'), because then all men would be excluded, although they are included in the universal idea

of 'animal' in our intellect. We thus see that the Platonic Ideas or essences either do not correspond to the universal ideas as we have them or they violate the Principle of Contradiction.

Besides, many Platonic essences would exist as realities although they possess *no positive entity*. 'Sickness,' for instance, is a universal idea, applying to all sicknesses as a class and to each particular sickness as an individual case. But 'sickness' is nothing positive; it is a non-entity, a mere privation, because it is the absence of health in someone who should normally be healthy. Although it lacks reality and entity, it would have to exist as a positive essence in the Platonic world of Ideas. But a non-entity cannot exist without being an entity; a nonentity, however, which is an entity, is a contradiction in itself. What has been said here of 'sickness' applies with equal force to all negative and privative ideas, as 'darkness,' 'lameness,' 'insanity,' 'death,' 'absent-mindedness,' 'blindness,' and the like.

Platonic ultra-realism is thus seen to be untenable, because it is self-contradictory. The noumenal world of Ideas is a fiction. Since the 'essence' or 'datum' of *critical realism*, as interpreted by some of its proponents, is extra-mentally 'universal,' outside the conditions of time and space, it is similar to Plato's Idea and as such is also self-contradictory.

EMPIRIC ULTRA-REALISM, AND ANY EXTREME REALISM WHICH follows its fundamental principle, cannot escape absurd consequences. It maintains that the universal essences

exist, not in a Platonic noumenal world, but *in the individuals themselves*. The consequences are fatal to the theory.

According to this view, a numerically single universal nature, corresponding to the universal idea in our intellect, exists in the individual members of a class; this universal nature or essence is thus a being which is really and actually 'one-in-many.' However, this universal nature must be either *really and only one* (universal) in all the individuals, so that they differ in nothing but accidentals, like color, shape, acts, etc.; or this nature must be *individuated* in each member of the class, so that the individuals are different from each other by possessing a complete individual nature distinct from that of the others.

Suppose we accept the first alternative. It would follow, for instance, that there are no 'individual men' in the world, but only a single 'universal man': we would have 'man-in-general,' but no 'individual human natures.' In that case the 'universal man' would indeed be one and universal, but it would not be '*one-in-many*'; as such there would be no correspondence between our idea and this nature, because our idea represents the nature as being present in all and in each. Besides, such a view is contrary to all our *experience*. Our experience testifies beyond any doubt that we possess a distinct human nature of our own. Each of us has his own body, his own mind, his own thoughts and volitions and emotions and perceptions and loves and hates and ailments. We are conscious that we do not possess a single universal human nature in common with all other men, so that together we are a numerically single 'universal

man.' To assert the contrary is to make our most intimate experience nothing but an illusion.

Then let us accept the second alternative, namely, that this universal nature or essence is *individuated* in each member of the class, giving to each a complete individual nature distinct from that of the others. In that case the *unity and universality* of the supposedly 'universal nature' would be destroyed. There would indeed be *many* individual natures, but there would not be 'one-in-many.' No matter which way the universal nature or essence is viewed and interpreted, it can never be '*one-in-many*' as an existing reality: it will either be 'one' and not 'many'; or it will be 'many' and not 'one.' To assert that it could be 'one' and 'many,' universal and individual, at the same time, is a contradiction in terms.

Logically, this form of ultra-realism, like any form of extreme realism, leads to *monism* and *pantheism*. If the specific nature of man is really universal and one in all men, then the generic nature of 'animal' must be one for all men and brutes taken together; men and brutes would no longer be distinct in nature, but form one 'universal animal.' Animals and plants would form one 'universal living being.' All living beings and inorganic substances would form one 'universal material substance. All material and immaterial substances would form one 'universal substance.' All substances and accidents would form one 'universal being.' There would be no *individuals or classes* at all, but a single reality and being: that is monism. And since God and the world agree in the concept of 'being,' either God must be identical with the world, or the world identical with God:

that is pantheism. All individuality of things is destroyed in this way; and thus the fundamental tenet of this form of ultra-realism, namely that the universal essences are found *in the individuals*, is abandoned. The theory has destroyed itself.

NOR IS *MONISTIC ULTRA-REALISM* CAPABLE OF AVOIDING ABSURDITY and contradiction within its theory. Monism, as a theory of being, belongs to ontology and cosmology, separate departments of philosophy; here it will be treated merely as a possible explanation of the validity of our universal ideas.

Monism, whether pantheistic or naturalistic, states that there exists but 'one sole reality,' common to all things; the things in the world are but parts, modes, or manifestations of the Absolute in its process of evolution. This, however, is contrary *to experience*. For one thing, we ourselves are conscious that we are *individuals* and subsisting *substances* in our own right, and not mere parts or modes or appearances or manifestations of one single reality. We are unitary beings, closed off in our entity from other beings, the subjects and causes of our own actions and reactions, and our personal Ego is clearly perceived to be distinct in its consciousness from that of other Egos. Our body, too, manifests itself to our minds as being different in entity from other bodies in the universe; it acts upon them and is acted upon by them, and in no way is it ever perceived to be one in being with them. This is unintelligible and inexplicable in the theory that all things form a single absolute being in which all are identified.

If monism were true, the electron, the stone, the amoeba, the elm, the mosquito, the whale, man, the sun, in fact *all mundane objects*, would consist of one self-identical reality, forming a single being and a single nature. In that case, however, our *consciousness* should reveal this absolute identity of nature between ourselves and the things in the universe, and it should be incapable of making an objective distinction between mind and matter, thought and thing, man and the world, the Ego and the non-Ego. Our empirical knowledge, whether obtained through external or internal experience, testifies that the world consists of a *plurality* of individual beings and not of a universal and absolute reality which is one in them all. *E. G. Spaulding* rightly observes that the empirical method “is a procedure that leads to the conclusion that monism of any kind can be grounded only artificially, and that a pluralism of many entities, of many kinds, in many different *loci*, is the only ontology which stands the test of empirical investigation.”¹ Either the Absolute, then, does not exist as monism claims, or our entire knowledge is essentially an illusion. The latter alternative we cannot accept without falling into skepticism. Consequently, the monistic Absolute must be rejected as a mere assumption.

Ultra-realism, in whatever form, is thus seen to be utterly at variance with experience and reason; as such it fails to solve the problem of the universals.

CRITIQUE OF NOMINALISM

Nominalism is the reverse of ultra-realism: it denies the universal altogether. The essences or natures are not extra-mentally universal, nor are our ideas intra-mentally universal. Our ideas are as individual as the things we perceive with our senses. Modern empiricists consider our intellectual knowledge to be nothing more than a refined sort of sense-knowledge; this being so, it is obvious that our ideas cannot really be 'universal,' representing a content which is strictly 'one-in-many,' but must be as individual in character as the sense-image itself. At best, we can have 'general images' or 'composite images,' a product of several singular sense-images fused together into a vague, indefinite representation, something like the composite photograph resulting from a number of superimposed plates. The only thing that is strictly universal is the *name*, or *word*, and that is used merely as a 'label' to designate a number of objects grouped according to some arbitrary pattern. Thus names or words, nominalists say, designate and represent *individuals or a collection of individuals*, but never represent anything which is mentally applicable to a class as a whole and to each individual belonging to that class. But in this they are wrong. A little reflection will prove this.

Names and words are *signs* and have a *meaning*; they are signs of *ideas* and they derive their meaning from the *content* of the ideas for which they stand. And since the ideas stand for things, names and words are also used to designate things. Now, if we can show that names and words are used to designate something which is conceived by the intellect as being 'one-common-to-many,' we thereby

prove that we really have *universal* ideas. And that is precisely what takes place.

We have names which stand for *singular* objects: 'Peter is a man,' 'Homer was a poet,' 'Plato was a philosopher.' Here the subjects represent a single thing. Other names stand for collective objects: 'The library is large,' 'the army marches on,' 'the herd is scattered,' 'the nation is in revolt,' 'the city is celebrating.' Here the subjects represent a number of individuals taken together *as a group*, but the statements do not apply to the individual members of the group. We have, however, many names and words which apply to a *class* and to *each member* of the class. Take the word 'man.' By 'man' we mean a 'rational animal.' This word represents the class as a class and the individual human beings belonging to the class. If we say 'Man is mortal,' just what do we mean? We mean that 'all men' taken together as a class 'are mortal' and 'each individual man' taken separately 'is mortal.' So, too, when science states that 'The living cell has immanent action,' it does not mean that a single cell or a mere collection of cells, but 'all cells' as a class and as individuals 'have immanent action.' Again, zoology tells us that 'the horse is a mammal.' The word 'horse' here does not designate a single animal like Man-O'-War, nor a collection of animals like a herd, but the whole class of equines and each member of that class. Such statements show plainly that these subjects have a content which are conceived as 'one-common-to-many.' And since words and names stand for ideas, our *ideas* have a content which is conceived as 'one-common-to-many.' That, however, is what is meant by a *universal idea*. We have,

then, ideas which are not merely singular or collective, but truly universal.

Nominalists admit the universality of our names and words, but deny the universality of the ideas for which they stand. *N.O. Losskū* refutes the contention of the nominalists that the name gives rise to the class. He says: "The contention is that the grouping of things into classes is not in any way determined by the properties of the things themselves, but is due to names. The name gives rise to a class of things, and it is not the class of things that attracts a name to itself. A rejoinder at once suggests itself, which, in spite of its seeming to be almost ironical, is nevertheless very much to the point. If the grouping of things into classes is determined by names — understanding by a name not a universal element but something created afresh in every single act of utterance — how is it that a name is never associated with groups of *heterogeneous* things, such as tiger, coffee pot, candle, and birch tree, but always with groups of *homogeneous* objects — homogeneous not merely in the sense of being connected with one and the same word? The only answer is that we associate with a name not anything which we choose, but only things which *resemble* one another. This, however, means that the name merely assists in the final crystallization of a general idea, and that the essential condition of things being grouped into classes is the *resemblance* between them."²

The fact is, that the intellect recognizes this resemblance of objects among themselves, groups the *many* into one idea, which is now universal, and uses a word or name to designate the idea. Only because we have universal *ideas*,

have we also universal *names*. If nominalism were correct, we should have no universal names, since we have no universal ideas. To have universal names without universal ideas for which they stand, is contradictory. But we have universal names; consequently, we have universal ideas. Nominalism must be rejected, because it maintains that names and words can have a universal significance without deriving this significance from the only source from which it can be derived, namely, from the universal ideas of which they are the signs. The significance of any sign depends on the significance of the thing signified. Hence, the *universal* significance of the *name* depends on the *universal* significance of the *idea*. Ideas are thus universal, and nominalism is false.

CRITIQUE OF CONCEPTUALISM

Extreme realists admit that we have ideas which are universal and claim that the things to which they apply are also universal. Nominalists deny the existence of universal entities and also deny that we have genuinely universal ideas in the mind. *Conceptualists* deny the universality of extra-mental entities as existing in nature and they admit that the intellect has genuinely universal ideas which are expressed in universal names or words. However, because the objects in the world are singular and not universal, they claim that our universal ideas can have *no objective value*. In other words, since the objects are singular while the ideas are universal, there is nothing in the objects themselves which would correspond in any way to the

content of the universal as 'one-common-to-many.' The universality of the idea is a *purely subjective product* of the mind, *without a foundation* in the things themselves which would entitle the mind to group a number of individuals under one (universal) idea. Hence, the universal idea can give us no genuine knowledge of the real nature of the things.

Conceptualists go too far when they assert that there is *no foundation* in things for our universal ideas and consequently that the content of these ideas as 'one-common-to-many' is purely subjective in character. If this were so, then the content of the universal idea would neither be *derived from* the individual things nor applied to the individual things. If we can show that they are derived from the individual things through sense-perception and are really applied to individual things as they exist in nature, then we have proved that universals have a *foundation* in these things and possess objective value. That indeed is the case.

This is clearly demonstrated by the fact that our intellect can form no universal idea of sense-qualities proper to a certain sense-faculty, if this sense-faculty has always been absent. A person born blind, for instance, cannot form a genuine, universal idea of light or color; and a person born deaf has no idea of what is meant by sound or music. The same is true of any other sense-quality. Whence do we derive our universal ideas of 'man,' 'plant,' 'dog,' 'star,' 'table,' and other objects, except from a previous perception of these things? Our ideas are based ultimately on sense-perception, not on purely intellectual activity; that

is why our ideas of *immaterial* things, like the soul, God, spirit, will, and the like, are so inadequate. Hence, conceptualists are wrong when they state that our universal ideas have no foundation in the reality of the objects; we *derive* them from these objects as they exist in nature.

That our universal ideas can be *applied* according to their content as 'one-common-to-many' to objects, is a matter of everyday *experience*. When I state 'Man is an animal,' I most certainly do apply the content 'animal' as a 'sentient organism' to each and every human being and to all human beings who live in this world; and that in a true, genuine sense. The statement has not merely value in my mind, but also in the order of *reality*: men actually *are* 'sentient organisms.' And so with statements like 'The rose is red,' 'the gnat is an insect,' 'the table is round,' and with innumerable other statements which contain universal ideas: they represent facts and objects of the real order. Such statements could never be true, if our universal ideas had no foundation in the reality of the things themselves.

That the *natural sciences* apply the universal ideas incorporated in their *classifications* and *laws* to the physical world is too obvious for serious dispute. The classifications of animals, plants, and inorganic substances have not only a subjective value for the mind; they really fit, as classes and types, the things of nature. And how could it be otherwise? Science derives its universal ideas of classes and types from its research into the beings which exist in the material world. The only reason why it groups such beings into classes and types is because it finds something 'common-to-many' in them; there is thus a foundation or ground *in the*

things for the formation of its universal ideas. So, too, with its *laws*. They represent generalizations based on the behavior of physical bodies. If these bodies did not act uniformly and constantly, science could never formulate such laws, nor would the laws of science apply to them in their respective fields. If scientists can and do predict the actions of physical bodies in nature, this is possible only because these laws have a foundation in the reality of these bodies and actually apply to them independently of the universalizing function of the mind. To deny this is tantamount to denying the validity of all science; and that would be ruinous of all knowledge of the physical world. Skepticism must inevitably follow.

Many conceptualists accept the conclusion that intellectual knowledge is practically an illusion. *Bergson* and *William James* do this in consequence of their anti-intellectualist doctrine of pragmatism.³ *Kant* and his disciples, although they attempt to establish the validity and necessity of scientific knowledge, are compelled to admit that all scientific classifications and laws have no objective, but only subjective, value. This follows, of course, with logical consistency from their theory that the reality of things-in-themselves is unknown and unknowable; the only objects we can know are the phenomena. The universality of our ideas is due to certain innate *a priori* forms or categories of the intellect, which are purely subjective in character and are imposed by the mind upon the manifold of sense; as such, then, they can have no objective value.⁴ But if the natural sciences are invalid as objective representations of the physical world and are nothing more

than subjective constructions of a fictionizing intellect, all knowledge and philosophy is doomed as illusory. That is the logical outcome of a consistent conceptualism; and that we cannot accept, because it means intellectual bankruptcy. Conceptualism must, therefore, be rejected as a false theory.

CRITIQUE OF MODERATE REALISM

A number of conclusions can now be drawn. Extreme realism is correct in asserting the presence of universal ideas in the mind; but it is wrong in assuming that realities exist in the world which are objectively universal as entities. Nominalism is correct in denying the existence of universal entities in the world; but wrong in denying the existence of universal ideas in the mind. Conceptualism is right in denying the universality of entities in the world and in affirming the universality of ideas in the mind; but it is wrong in asserting that there is no foundation for our universal ideas in the objects of the world. The final conclusion, then, must be that we have universal ideas in our mind and that they have a foundation in things themselves. This last is the teaching of *moderate realism*, and the truth of moderate realism is thus established. A more positive proof, however, is required. With experience and reflection as guide, it will be necessary to show how universal ideas are developed from sense-perception through a process of abstraction.

It is in this process of *abstraction* that we find the solution of the problem of the universals. In order to

understand it properly, we must begin with sense-perception. The things in this world are *single* beings, *individual* natures. Universal entities do not exist outside the mind in the material universe or anywhere else; this was proved against extreme realism. These individual beings possess many characteristics peculiar to themselves, so that one differs from the other to such an extent that no two are totally alike in *every* respect; each nature is thus individualized, numerically one, and incommunicable to others. Consider man. Each person has his own individual nature, concretely determined by color, weight, size, shape, etc., so that he is distinguishable from every other person. Our senses perceive these individuals in their concrete determinations, and the phantasm or sense-image represents them with all their concrete similarities and differences.

Once the phantasm or sense-image is made, the *intellect* begins to operate. It gives its attention to this and that trait and attribute and perceives their *what-ness*, i.e., that which makes them to be 'what' they are and without which they could not remain 'what' they are; it is the essence of these things. This applies to substances and accidents; in fact, to everything that exists. Take again the example of man. Amid all the characteristics of individual human beings, the intellect is aware that the elements of 'a bodily, living, sentient, rational substance' are present in each individual all the time and *must* be there. A man would cease to be a 'man,' if a single one of them were missing; these elements, therefore, constitute man's essence or 'what-ness.' The other characteristics, like weight, color, size, shape, etc.,

are not necessary; they could be missing in some or all individuals, without a man ceasing to be a 'man'; in other words, these determinations, though present in the individual, are not part of his 'essence' as such.

Here, then, we have the basis for the origin and validity of *universal ideas*. From the sense-image, representing the individuals in all their concrete similarities and differences, the intellect *abstracts* or draws forth an intellectual image of the essence, leaving out of consideration the nonessential characteristics which distinguish one individual from the other. This essence, as will be noted, is a *reality*, and it is actually present in the individuals independent of our thinking, though *not in that abstract form* in which it is represented by the intellect. The real individual, as it exists in the physical world, has all the elements of this essence *plus* its concrete, nonessential, differentiating characteristics, while the intellect leaves the latter aside and selects only the essential elements or essence. This essence, as it exists in the intellect, is thus stripped of everything which is not necessary to the 'what-ness' of the thing and is now *abstract*. This abstract representation or *idea* in the intellect is, as far as it goes, a true representation of the essence of the thing existing in the objective world, even though it leaves out of consideration the various differentiating characteristics which accompany this individual essence in reality. And since this essence (for instance, man as 'a bodily, living, sentient, rational substance') is recognized by the intellect as being the same with *the sameness of a perfect likeness* in each individual taken singly and in all individuals taken as a class, this

comprehension or content of the abstract idea is such that it will apply to the class as a whole and to each individual as a member of that class. In other words, the content, though one, is applicable to many: the content is 'one-common-to-many.' And that is what we mean by a universal idea, namely, an idea whose content represents an essence which is found to be present in many, so that all, individually and collectively, possess the same (not identical, but *like*) common essence. Such an abstract idea is, therefore, a *true universal*.

There are two kinds of universal ideas: *direct* and *reflex*. A consideration of what has just been said will show the difference between these two types of universals. When the intellect abstracts the 'essence' from the sense-image, it considers at first *nothing but the essential elements* which constitute the thing: this and nothing more is before the intellect through the process of abstraction. At this stage the intellect does not consider whether this essence is 'one' or 'many'; it is interested merely in the 'essential elements' *as such*, without reference to the number of individuals to which they can or cannot be applied. The intellect contemplates the essence in an *absolute* fashion, as it is in itself, simply as the 'what-ness' of the thing. Since, however, the essence or 'what-ness' represented by the idea is such that it *could be applied* by the intellect to one and many at the very moment the abstraction is made, this idea is already a true universal; but the intellect does not *as yet* reflect on this possibility, nor does it make the actual application. Hence, this idea, considered as the immediate product of abstraction, is called a 'direct,' or 'potential,' or

‘metaphysical,’ or ‘fundamental’ universal. This type of universal, therefore, expresses merely the essence or ‘what-ness’ of a thing as it is *in itself*, prescinding for the time being from its singularity or multiplicity.

After having formed the abstract idea of the essence, the intellect *compares* this essence with the essences of *similar* objects; and by means of this act of comparison it becomes aware that this essence is not only found in this one object, but is *predicable of many* similar objects. The content of the idea representing this essence is recognized to be such that it is capable of being realized in any number of individuals: it is ‘one-common-to-many.’ In this manner the intellect now *formally universalizes* the original idea of the essence abstracted from the sense-image, after having seen that it is applicable to the whole class and to every individual member of the class. This type of universal idea is called a ‘logical,’ or ‘formal,’ or ‘reflex’ universal. It will be noted that the ‘direct’ universal refers merely to the *comprehension* of the idea, i.e., it expresses an essence which, though in itself ‘common-to-many,’ is not considered as common to many; while the logical’ or ‘formal’ universal refers to the *extension* of the idea, i.e., it expresses an essence which is ‘common-to-many’ and is considered precisely in so far as it is common to many. In other words, the ‘direct’ universal possesses a *potential* universality, while the ‘logical’ universal possesses a *formal* universality in the intellect. The former represents the essence considered *in itself alone* as expressing the ‘what-ness’ of the thing thought about, without regard to whether it is singular or multiple; the latter represents the essence as

formally universal, as something which is applied or is at least applicable to 'one-and-many.'

It is important to realize this distinction between the direct and reflex universal, because it enables us to understand how universals can be predicated of individuals and still furnish us with a true knowledge of the things in their objective reality. In predicating a universal of the individual things, we apply the *content* expressed in the *direct* universal to the object, because that content represents the essence as such *without the mode of universality* attached to it. In the reflex universal the mode of universality always accompanies the abstract essence, for the reflex universal considers this essence precisely as universal, as 'one-common-to-many.' In other words, we predicate the absolute essence of the individual, and not the 'universalized' essence, so that the *universality* of the idea is not applied to the absolute at all. This idea of the essence, considered in itself alone and absolutely, is a true representation of the essence as it exists in the individual and can, therefore, be truly applied to it. Error would enter into our predication, if we applied the content of the abstract essence and *also* its universality to the individual things, because these things are not universal but singular in reality. We thus safeguard both the singularity of the individual and the truth-value of our universal ideas. That we 'universalize' the essence and consider it (in the reflex universal) as 'one-common-to-many,' is merely a *logical mode* of our thought-process and does not change the content in any way: the *content* remains *real*, while the

universality is a *logical mode* (*ens rationis*) superadded to it.

While the 'universality' of the abstract essence is thus a product of the mind and is not found in the real essence as it exists in nature, the intellect observes a *foundation or reason* in the things themselves which entitles it to universalize the abstract essence in this manner. This universality is founded on the real *similarity* of essence existing between different things, so that the intellect can group them into a *class*. These objects are really alike in their essential elements; all men, for instance, are really 'bodily, living, sentient, rational substances.' After comparing them and seeing the complete likeness of their essences, the intellect groups them into a class and expresses the whole class by means of a *single* (universal) idea; and this idea is now capable of being applied to the whole and to every member of the class - for example, to John, James, Plato, Napoleon, and to all men taken together. Their essences are not identical, but they are really and truly similar; consequently, the objective ground or foundation for the formally universalized idea lies in the similarity of the essences embodied in all the members of the same class. Therefore, the intellect is justified in stating 'John is a man,' applying the universal idea 'man' to the individual 'John,' because it thereby predicates, not the universality, but the content of the idea 'man' to 'John,' and this content is perceived to be *actually realized* in him. While, then, the 'universality' of the abstract idea is thus seen to be a product of the mind, there is a real foundation in the things themselves entitling the intellect to

universalize this idea and make it 'one-common-to-many.' Both the *things* and the *intellect* contribute their share in the formation of universal ideas: the things contribute the *material or content*, namely the 'what-ness' or 'essence,' and the intellect contributes the *form or mode*, namely the 'universality.' Hence, the universals are real from the standpoint of their material or content, but not according to their form or mode; the form or mode, however, has a foundation in the things themselves. The whole situation can be summed up as follows: In the real order the essence is actually many, but potentially one; in the intellectual order it is actually one, but potentially many.

Reflection and introspection thus prove that the universal as such is a product of the mind with a foundation in the things. Or, as St. Thomas Aquinas expresses it: 'Universals are *formally* (as such, i.e., as universals) in the mind, *fundamentally* in the things themselves.' That is the solution of the problem of the universals as offered by *moderate realism*. If we compare this solution with that offered by the opposing theories of ultra-realism, nominalism, and conceptualism, we will find that it alone explains the obvious singularity of the individual things in nature and the objective value of our intellectual knowledge as applied to these things. Moderate realism is the only correct theory of the universals.⁵

From the above it will be clear that our universal ideas give us a true and genuine (though naturally incomplete and inadequate) insight into reality; they are a valid source of scientific knowledge, and the truth-value of our

intellectual ideas is thus critically and philosophically established.

SUMMARY OF CHAPTER XIV

The validity of our intellectual knowledge depends on the validity of the universals, because our knowledge, to be true, must conform to reality. Different theories have been devised to solve the problem: extreme realism (ultra-realism), nominalism, conceptualism, and moderate realism.

1. *Critique of Extreme Realism.* As a general refutation of ultra-realism, it may be noted, first, that our knowledge need not correspond with reality in *every respect*, and, second, that there is *no empirical evidence* of any kind to show that universal essences exist.

Against *Platonic* ultra-realism. If generic universals actually existed, we would have 'animals' which are neither rational nor non-rational, 'organisms' which are neither sentient nor non-sentient, etc. There would also be universal realities *without entity*, such as are expressed in privative ideas, like sickness, lameness, insanity, etc.

Against *empiric* ultra-realism. If the universal essence is considered to be *really and only one*, it would mean, for instance, that there are no individual men, but only a 'universal man' or 'man-in-general'; that is contrary to our experience, since we are conscious of our own individual nature. If this essence is considered as *individuated* in each member of the class, it would not be universal. Every form of ultra-realism leads logically to *monism* and *pantheism* through the universalization of 'being.'

Against *monistic* ultra-realism. It is contrary to our experience, since we are individual substances with an

individual *consciousness*.

2. *Critique of Nominalism.* Names are signs of ideas. But our names are universal, applying to a class and to each member of a class. Consequently, we have universal ideas for which these names stand. If the name, and not the property of things, determined the grouping of objects into classes, we could not explain why only *homogeneous* things are thus grouped.

3. *Critique of Conceptualism.* Universal ideas must have a foundation in the reality of things, because they are *derived* from individual things and *apply* to them. A person born blind has no genuine idea of color or light; this shows that our ideas have a foundation in the things. Experience proves that we really apply these ideas to things, as when we say that 'man is an animal'; we actually mean that the content of the idea 'animal' is found in 'man.' The *classifications* and *laws of science* really apply to things, because they are derived from the things in nature.

4. *Critique of Moderate Realism.* From the above it must be clear that universal essences do not exist; but we have universal ideas in the mind and they have a foundation in the individual things: that is moderate realism. Through our senses we obtain a *phantasm* of the individual essence in all its concrete determinations. The intellect now makes a vital similitude of the object, by *abstracting* the essence or 'what-ness' of a thing, leaving out of consideration the nonessential characteristics. This 'essence' is actually present in the individuals, but not in this abstract form; individuals are alike through *similarity* of essential elements. The content (abstract essence) is expressed in

the *direct* universal and is predicated of the individual objects. The *universality* ('one-common-to-many') is expressed in the reflex universal and is not predicated of the individual objects. The 'content' is *real*, but the 'universality' is a *logical mode* (*ens rationis*). The similarity of things is the foundation or ground which entitles the intellect to universalize' the abstract essence, considering it as 'one-common-to-many.' Hence, the axiom: Universals are formally in the mind, fundamentally in the things.

I am an ontological nominalist, I recognize the objective reality of structure and relations. This flows from my physical realism. Similar things have similar properties and structures. And, when we think them, we can think them in terms of the same predicates. The predicate which will disclose one will disclose the other. It has a one-many capacity of disclosure. I am an ontological nominalist because I see no adequate reason to postulate a peculiar entity called a universal to account for these similarities. To me, the ultimate ontological fact is the existence of a multitude of similar substances able to combine in similar patterns and have, in such combinations, similar properties. And this, I take it, is the path science has actually chosen." This is moderate realism. Although Sellars impugns the teaching of Aristotelianism and Thomism, his own theory of knowledge, as given in the *Essays in Critical Realism* (pp. 217 and 218), is closely akin to these systems. (See Edward F. Talbot, *Knowledge and Object*, Catholic University,

Washington, D. C.) Universals thus give us a true insight into reality and are a valid source of knowledge.

5 Roy Wood Sellars, in *The Philosophy of Physical Realism* (Macmillan Co., 1932), calls himself a 'logical conceptualist' and an 'ontological nominalist.' It is unfortunate that his use of the terms 'conceptualism' and 'nominalism' is at variance with the standard definitions of these theories as given in history, because as a matter of fact the expression of his own views and of the views of some other critical realists in this matter is identical in substance with the 'moderate realism' of Aristotle and St. Thomas (see pp. 155, 156; 173-175). The following quotation from page 175 shows this plainly: "It will be noted that, while I am an ontological nominalist, I recognize the objective reality of structure and relations. This flows from my physical realism. Similar things have similar properties and structures. And, when we think them, we can think them in terms of the same predicates. The predicate which will disclose one will disclose the other. It has a one-many capacity of disclosure. I am an ontological nominalist because I see no adequate reason to postulate a peculiar entity called a universal to account for these similarities. To me, the ultimate ontological fact is the existence of a multitude of similar substances able to combine in similar patterns and have, in such combinations, similar properties. And this, I take it, is the path science has actually chosen." This is moderate realism. Although Sellars impugns the teaching of Aristotelianism and Thomism, his own theory of knowledge, as given in the *Essays in Critical*

Realism (pp. 217 and 218), is closely akin so these systems. (See Edward F. Talbot, *Knowledge and Object*, Catholic University, Washington, D. C.)

Chapter 15

THE TRUTH-VALUE OF NECESSARY JUDGMENTS

WE HAVE ESTABLISHED THE OBJECTIVE VALUE OF OUR IDEAS. THEY have a 'mode of universality' in the intellect, but they express a 'content of reality'; that which they represent actually exists in the things represented. This naturally leads us to inquire into the validity of our intellectual *judgments*. Judgments consist of ideas. A judgment is a mental act whereby we assert the agreement or disagreement between two ideas. And since our ideas stand for things, what the judgment asserts of ideas it actually means to assert of the things represented by the ideas. When I say, 'This table is square,' I claim that the two ideas 'table' and 'square' are in agreement with each other; but I also claim that the *reality* expressed by the idea 'square' is actually found in the *object* expressed by the idea 'table,' so that the extra-mental 'table' is extra-mentally 'square' in the domain of physical nature. And when I say that 'Gold is not iron,' I not only disunite these two ideas in my intellect, but I also assert that 'gold' and 'iron' are not identical in their physical reality. The truth of such a judgment will depend upon the agreement of the judgment with the *fact* enunciated.

There is no real problem in this. As long as the intellect can acquire a knowledge of the reality of things and represent them by means of its ideas, it can pass a judgment upon the identity or non-identity of things by means of ideas used as subject and predicate. But there is one phase of the judgment which involves a real problem for the philosopher. We derive our ideas from sensible objects. And sensible objects are concrete, individual, changing, temporal, and contingent; they are neither eternal, immutable, nor necessary. However, many of our judgments have the characteristic that they appear to us to be *eternally, immutably, and necessarily true*. Whence do they obtain this character? And how can they be a true representation of reality?

STATEMENT OF THE PROBLEM

We form various kinds of judgments. For example: 'The sun is shining today'; 'three boys are skating on the pond'; 'I took a stroll this afternoon.' These statements express facts known through *experience*; they are true, but they *need not* be true and *could be different*. There is no necessary connection between the subject and predicate of these statements: the sky could be overcast; the boys need not go skating; I did not have to go for a stroll. That we connect these particular predicates with these particular subjects, is simply because the facts happen to be so and not because they must be. The facts are contingent and could easily be otherwise.

Other judgments are such that their truth must be so and can absolutely not be different. Take these arithmetical statements: ' $2 + 2 = 4$ '; ' $5 + 4 = 6 + 3$ '; ' $7 + 3 = 15 - 5$ '; and the like. Or geometrical axioms, such as: 'Two parallel lines can never meet'; 'the whole is greater than any of its parts'; 'the sum of the angles of a triangle are equal to two right angles'; and so on. And also the philosophical principles: 'A thing can-not be and not be the same thing at the same time' (Principle of Contradiction); 'a thing either is or is not something' (Principle of Excluded Middle); 'a thing must have a sufficient reason for its being and existence' (Principle of Sufficient Reason); 'whatever happens or becomes must have a cause for its happening or becoming' (Principle of Causality). Such principles are adjudged to be true independently of all existential conditions and experience. They are not only true here and there, now and then, for this and that mind; they are *eternally, immutably, necessarily true*, everywhere, always, and for every mind. The connection between these subjects and predicates is adjudged to be *absolute* and *universal*, removed from any possibility of change or error. Our intellect has no choice in the matter; it must give an unequivocal assent to these so-called *first principles*, without being able to prove them by anything like a strict demonstration.

Now, why must the intellect assent to them this way? What is it that influences and *forces* the mind to assent to these judgments? Does the motive which constrains our intellect lie within the *subjective* constitution of the intellect itself, so that it must judge in this fashion simply because its laws of thinking are made that way; or does the motive lie

in the *objective* nature of these truths themselves, so that they reveal themselves with evident clarity to our intellect and thus force it to make these judgments? In the first alternative, first principles are true merely for *our* minds and need not be true in themselves; in the second alternative, these principles are true everywhere, always, and for *all* minds without exception, because they are objectively true in themselves independently of our own thinking. In the first alternative, we 'make' them to be true; in the second alternative, we 'discover' them to be true. In the first alternative, their truth-value is restricted to our *intellect* and is purely subjective; in the second alternative, their truth-value applies to *reality* and is objective.

This shows the *importance* of the problem involved in the knowledge of such principles. These principles form the foundation of all scientific and philosophic knowledge, as will be readily observed. Without the objective truth of the Principles of Contradiction, Excluded Middle, Sufficient Reason, and Causality, our entire knowledge of physics, chemistry, astronomy, biology, and all other natural sciences would be without a rational basis in *reality*; they would be subjective constructions of our mind and as such might or might not correspond to the facts of physical nature. Without the objective truth of the axioms of arithmetic and geometry, these sciences would be a mere figment of the mind and might be inapplicable to real things. If these principles were subjective in character, the structure of our intellectual knowledge would lack necessity and universality as a representation of reality; as such they would cease to be real science and real philosophy, because science and

philosophy are supposed to give us certain knowledge of ourselves and of the world. It is, therefore, of prime importance for us to know whether the *necessity* which we perceive in the logical connection between the subject and predicate of first principles is objective or subjective, i.e., whether their logical connection and truth is due fundamentally to our *intellect* or to the *reality expressed* in them.

THE THEORY OF ASSOCIATIONISM

The *empiricists*, as we have seen, admit nothing but sense-knowledge of phenomena. For them there is no such thing as a supra-sensible intellectual knowledge. Ideas are but refined sense-images; consciousness is a 'bundle' or 'series' or 'stream' of perceptions. The mind is nothing permanent and abiding, and it can never transcend its own internal states. Since the mind itself and all phenomena are but passing, changing, contingent realities, it is obvious that there can be no permanent and necessary knowledge in any form. Their theory of sensism precludes all knowledge which would possess a universal and necessary character. Yet it cannot be denied that we consider these axioms to be necessarily and absolutely true. What is the origin and explanation of this general conviction? It is a fact and must be accounted for.

Hume finds its origin and explanation in the *association* of our ideas. Certain ideas or images are always experienced as going together; certain phenomena always appear in a regular sequence of time or in a definite

contiguity in space. Thereupon we uniformly and continuously associate these things together in our mind. This is done in virtue of the *law of association* inherent in the mind itself, because the mind is so constituted; and this is a subjective law with a purely subjective result. Consequently, the 'necessity' which we experience relative to the logical connection between subject and predicate in these principles is not due to anything coming from the reality represented in these judgments, but solely to the *associating force* existing in the mind. It is a subjective and *psychological*, not an objective and *ontological* necessity. The mind does not judge these principles to be true, because it *sees* that they cannot be otherwise; it *cannot see* them to be otherwise, because the mind in its present constitution must judge them to be true. There is nothing *intrinsically* impossible in $2 + 2$ being 5 or 3, or in a circle being square or hexagonal, or in parallel lines meeting in a point, or in a triangle having six right angles, or in an object having contradictory properties, or in a thing coming into existence without a cause. As a matter of fact, according to Hume, Mill, and empiricists generally, the Principle of Causality is nothing but a mental expression of 'invariable sequence': because we observe things following each other invariably in time, we simply judge that the preceding object 'causes' the one following. This, however, is solely due to the fact that they are invariably 'associated' in our sensations as prior and posterior. If we think that an absolute necessity exists in the connection between these subjects and predicates, so that these principles *must* be true for all times and in all places and for all minds, we are

harboring an illusion. There is no such objective necessity. For other minds, in other places, at other times, and under other conditions, such principles and axioms may have no truth-value at all; we, of course, according to the present constitution of our mind in its laws of association, must consider them as necessarily true and valid. Such is the theory of associationism in its attempt to explain the character of necessity which we perceive to exist in first principles and axioms.

This theory is false and fails to give an adequate account of the logical necessity existing in these judgments. If the theory were correct, we should perforce experience the same psychological necessity of judgment in *every case* where we observe a uniform and constant association of objects or ideas in our consciousness. This, however, is patently wrong. For instance, day follows night in an invariable sequence; but nobody would dream of asserting that the night is the 'cause' of the day. Here we see plainly that constant and uniform association does not in any way force us to the necessary judgment that night 'produces' day. So, too, we perceive that spring invariably follows winter; nevertheless, we do not judge for that reason that winter is the 'cause' of spring. Every time we lift our eyelids during the day, we invariably see; yet we do not think that the lifting of the eyelids 'causes' our actual 'seeing,' since we ascribe it to the power of sight residing in the organ itself. Hence, the necessity inherent in our judgment expressing the Principle of Causality is not derived from the subjective influence of the association of our ideas.

Even when we do assert the necessity of a causal interaction in physical phenomena, this *factual* necessity based on experience is very different from the *absolute* necessity we judge to exist in our first principles and axioms. We always observe, for instance, that water at sea level expands and solidifies at $+32^{\circ}$ F. and vaporizes to steam at $+212^{\circ}$ F. We say that water 'necessarily' does this. But we also know that this necessity is not absolute; water *could* act otherwise without destroying the nature of water or the foundations of our knowledge. But compare this judgment with the judgments 'A circle is round,' ' $2 + 2 = 4$,' 'everything must have a sufficient reason,' or with any other first principle, and the difference between the respective 'necessity' of these two types will immediately be apparent: the judgment about water freezing or vaporizing at these temperatures is factually and physically necessary, while the latter judgments are absolutely and metaphysically necessary, because we realize that the latter admit of no exceptions and *must* be true under *all* circumstances. But why the difference for our mind? We certainly never experience any exceptions to water freezing at $+32^{\circ}$ F. and vaporizing to steam at $+212^{\circ}$ F. Then, according to the law of the association of ideas, both types of judgments should exhibit the same sort of necessity. That, however, is not the case. Consequently, the association of ideas resulting from constant and uniform contiguity or sequence does not account for the necessity we perceive to exist in our judgments expressing first principles and axioms. Associationism thus fails in its attempt to explain the mental facts of our necessary judgments.

Moreover, it takes but a moment's reflection to see that this theory must *destroy all science*. The very foundation of science lies in the Principles of Contradiction, Sufficient Reason, and Causality. If these principles are valid only for our mind and do not apply with inviolable necessity to physical objects in nature, the scientist has no means of knowing whether his conclusions are objectively valid. And if he cannot be sure of this, the knowledge he acquires is nothing but a *purely mental construction* which may or may not agree with extra-mental reality. But science treats of physical systems, not mental constructions. If associationism were a true interpretation of the fact of mental necessity in our judgments about nature, science would be valueless as an explanation of physical phenomena. A theory, however, which destroys science must be intrinsically wrong.

THE THEORY OF FORMALISM

Kant was shocked by Hume's sensism and skepticism, since it destroyed the truth-value of science; it awoke him, as he himself says, from his "dogmatic slumbers." He felt he was called upon to save science. Kant was convinced that science gives us true knowledge, and the judgments resulting from true knowledge are genuinely universal and necessary. Since, however, true science must have an empirical content (i.e., be derived from experience), and since the empirical is only contingent and constantly changing, he naturally put to himself the question: How account for the *universality* and *necessity* so manifestly

exhibited in our scientific knowledge? Since the things of experience are only individual and contingent, Kant felt that the 'universality' and 'necessity' of knowledge could not be derived from the things of experience as such. Whatever, then, is 'universal' and 'necessary' in our knowledge cannot come from experience; it can come only from the *mind itself*. Kant considers all knowledge derived from experience as *a posteriori*, and all knowledge supplied by the mind itself as *a priori*; the latter is innate in the mind and independent of all experience. Even scientific induction cannot give us true and strict, but only assumed and relative, universality; a judgment of strict universality, in which no exception is admitted as possible, cannot be derived from experience, but must receive this strict universality from the mind. How, then, does scientific knowledge come about?

As our sensibility gives us objects to perceive, so our understanding gives us ideas or *concepts* of these objects of our sense-intuition. In order to have intellectual knowledge, therefore, our intuitions or phenomena must be brought under certain concepts or *categories* of the understanding; thereby these intuitions become intelligible. In this union of intuitions and concepts knowledge is produced. Just as 'space' and 'time' are the *a priori* mental forms which must be united to the *a posteriori* impressions in order to make intuition possible, so the 'concepts' or 'categories' are the *a priori* forms of the understanding which must be united to the phenomena or sense-representations in order to make judgment and thought possible. These 'concepts' or 'categories,' like 'space' and 'time' with regard to sense-

impressions, give *universality* and *necessity* to our thoughts and judgments and must, therefore, be in the mind prior to all experience and independent of all experience. There are twelve such 'categories,' according to Kant, and for each there is a specific type of judgment. They are:

<i>Categories</i>	<i>Judgments</i>	<i>Example</i>
Quantity:	Quantity:	
(1) Unity	(1) Singular	This S is P.
(2) Plurality	(2) Particular	Some S is P.
(3) Totality	(3) Universal	All S is P.
Quality:	Quality:	
(4) Affirmation	(4) Affirmative	S is P.
(5) Negation	(5) Negative	S is not P.
(6) Limitation	(6) Infinite	S is not -P.
Relation:	Relation:	
(7) Substantiality	(7) Categorical	S is P.
(8) Causality	(8) Hypothetical	If A is B, S is P.
(9) Reciprocity	(9) Disjunctive	S is either P or Q.
Modality:	Modality:	
(10) Possibility	(10) Problematic	S may be P.
(11) Existence	(11) Assertoric	S is P.
(12) Necessity	(12) Apodictic	S must be P.

These categories, of course, do not apply to the extra-mental things-in-themselves; they apply merely to the *phenomena* which are, as we have seen, subjective products of the union between the sense-impressions and the space-and-time forms. These categories are also *a priori* subjective mental *forms*, innate in the mind, and as such their application to the representations contained in the phenomena is the result of a subjective *law* of the mind;

they are not derived from experience in any way, but are in the mind prior to all experience. When we, therefore, make the judgment that 'The whole is greater than any of its parts' and consider that this judgment must be true in a strictly universal and necessary manner, then this absolute 'universality' and 'necessity' indeed transcends all experience and is valid for all times and places and minds; but this is only true of the 'phenomena' as a subjective mental product existing in the mind and does not apply to the extra-mental world of *things-in-themselves*. Our knowledge simply cannot reach to the noumena or things-in-themselves; they remain forever an unknown and unknowable X.

And therein lies the *fallacy of Kant's theory*. He does not succeed in saving science from Hume's skepticism. Science treats of the physical objects of the extra-mental world and not of mental constructions; Kant's world, however, is a world of phenomena, and these phenomena are mental constructions which give us no insight whatever into the nature and reality of things as they are *in themselves*. According to the ultimate findings of Kant's system, we can know nothing whatever about physical nature. He presupposes that physical nature exists in some form or other, because he postulates the existence of 'things-in-themselves' in order to account for our original chaotic sense-impressions; but what this physical world is like is an insoluble mystery. Such, however, is not the view of science. Science is convinced that it reaches *real things* outside the mind; according to Kant, this is impossible. The *laws* which science establishes are considered by scientists to be real

laws operating in physical bodies independent of our thinking; according to Kant, these laws merely relate to phenomena within the mind and not to nature at all. That Kant really drew this conclusion, can be seen from his *Critique*: "It sounds no doubt very strange and absurd that nature should have to conform to our subjective ground of apperception, nay, be dependent on it, with respect to her laws. But if we consider that what we call nature is nothing but a whole [*Inbegriff*] of phenomena, not a thing by itself, we shall no longer be surprised."¹ That this destroys the validity of science in its very foundations, must be obvious. While treating of the validity of sense-perception, we proved that our mind really transcends its own conscious states and perceives the external world; in this we proved that science is correct and Kant is wrong.

Kant distinguishes between 'synthetic,' 'analytic,' and 'synthetic *a priori* judgments. The *synthetic* judgments are based on experience, such as 'Bodies are heavy,' 'fire burns,' 'this circle is green,' 'the boy runs.' In these the predicate adds a new idea to the subject, and this idea is derived from experience; hence, they are styled 'synthetic *a posteriori*.' Some of these judgments express singular and contingent facts, like the last two examples. Others may express a universal and necessary fact, like the first two, but this is only an empirical, not a strict or absolute, universality and necessity, because exceptions are at least conceivable. The analytic judgments are not based on experience, but are always *a priori*. In them the predicate is always found to be contained in the subject, and an analysis of the subject will reveal the presence of the predicate; for

instance, 'Bodies have extension,' 'a circle is round.' These predicates do not increase our knowledge of the subject, because they are only 'explicative'; for this reason they are without value for science. In this they differ from 'synthetic' judgments, for the latter add a new idea (contained in the predicate) to the subject with a consequent amplification of knowledge. Not all 'synthetic' judgments, however, are valuable for science, because not all of them possess that *absolutely* 'universal' and 'necessary' character which is required for *scientific* knowledge. Some 'synthetic' judgments are entirely *a posteriori*; for instance, 'This circle is green,' 'the boy is running.' Others, though, express a universality and necessity which is *absolute*, and these admit of no exceptions even in thought; such are judgments like ' $7 + 5 = 12$,' 'action and reaction are equal,' 'a straight line is the shortest distance between two points,' 'whatever becomes must have a cause,' etc. Whence the absolute character of the universality and necessity of these 'synthetic' judgments? It cannot come from the contingent things, because these things are singular and transitory in nature. Consequently, it must be *a priori* and arise from the *intellect* itself: the intellect communicates this absolute universality and necessity out of itself to these judgments. These are, then, *synthetic a priori* and as such have absolute value for science. Thus Kant.

Many critics² have shown that Kant was not justified in designating these judgments as synthetic *a priori*: they are all synthetic (*a posteriori*) or analytic (*a priori*). But that does not concern us. We are here interested in his explanation of the *necessity* we attach to these judgments.

Even though the existence of such judgments be admitted, Kant fails to solve the problem of their absolute necessity. Of course, he asserts that this necessity imposed on the judgment by the intellect is absolute and therefore binding at all times, in all places, and on *all minds*. But we must not forget that it is *the individual mind*, according to his explanation, which contributes this necessity to the judgments; and this individual mind is as *contingent, singular, and transitory* as any other thing in the world. My mind could thus impose this necessity on my judgments *for me*, so that I could not think differently; but that would not mean that these judgments possess an absolute necessity *in themselves or for other minds*. According to Kant's own principles, my mind cannot transcend the phenomena of its own making; it is imprisoned within its own subjective world of phenomena. This being the case, it is impossible for me to know even the *existence* of 'other minds,' much less their *nature* and *operations*; they belong to the world of noumena, of things-in-themselves, and are forever excluded from my domain of knowledge. This being the case, I cannot know how these 'other minds' are constituted, nor whether they operate as my own mind does. They may, therefore, for all I can know about them, have an entirely different view of such judgments, because they may be differently constituted. What is the result, then, of Kant's theory? Simply this, that the absolute necessity of first principles and axioms is the product of my own individual subjective mind and is without any value, as far as I can know, for other minds. There would be indeed a *subjective, psychological* compulsion for my mind to think in this

manner, but I have no way of knowing whether this necessity applies to *all* other minds. That, however, is the precise character we observe in these judgments: they are valid for *all* minds. Since my own mind is singular, it cannot make these judgments absolutely necessary for all other minds. Kant's explanation, like Hume's, makes of this necessity a purely *relative and subjective* thing; and such a necessity destroys the objective character and value of all science.

Besides, of what value are judgments, and in particular the most *fundamental* judgments, such as the first principles and axioms are, unless they rest upon an *intelligent insight* into their truth? To accept them blindly, is assuredly not certain knowledge: we 'know' something when we 'see' or 'understand' it, and to 'know' the truth of a judgment means to grasp intelligently the exact relation between the subject and the predicate. If one denies that such an insight is required and asserts that a blind, subjective *necessitation* is sufficient to accept the truth of judgments, then *certitude has no rational foundation*, and we must despair of all knowledge and truth. Such is the logical outcome of Kant's theory of judgment. We do not make these judgments because we perceive the objective relation of subject and predicate, but because a blind, necessitating law of our mental constitution draws certain sense-intuitions under certain intellectually empty categories *prior* to our judgment, and we do not know why these particular categories were imposed by the mind on these sense-intuitions. Our 'knowledge' is thus as blind as the law that produces it. If this should be *scientific* and

philosophic knowledge, it is valueless, because it gives us no intellectual insight into the nature of the reality our judgments are supposed to represent. Kant might have saved himself the trouble of writing his *Critique*, for who knows under what subjective, blind, unknown, and unknowable necessity and law of his mind he was laboring when he wrote it.

THE THEORY OF EVOLUTIONISM

Spencer, realizing the weaknesses inherent in the associationism of the older empiricists and in the formalism of Kant and his followers, sought the solution for the obvious necessity of axiomatic truths in *evolution*. This necessity cannot be explained by the ordinary action of mental associations or mental forms, because the individual who makes these judgments under their influence is a singular, contingent being whose span of life is far too brief to acquire associations and mental forms valid for all times and for all minds. Spencer was convinced that long ages were required to mold the human mind in such a way that it accumulated certain *fixed forms of thought* through a process of *innumerable associations* repeated with *incalculable frequency*. In this manner the experiences of the race were crystallized into definite principles and axioms which now express an absolutely necessary relation between certain subjects and predicates in our judgments. Evolution, therefore, can produce what the individual cannot acquire. Heredity, of course, is the source of transmission for these accumulated individual experiences

and modifications for we must remember that, according to Spencer and the vast majority of evolutionists, the mind is only a mode of neural matter and thought a mode of neural action. In the field of knowledge they are empiricists and sensists. It is but natural, then, that they would turn to evolution for an answer to the problem.

This explanation is *inadequate*. At best, we would again have nothing more than a *subjective, psychological* necessity for making such judgments, while we clearly observe that these axiomatic truths are valid not only for the ideal order of the mind but also for the *objective order of reality*. They are thus seen to be based, not on the instinctive, habitual character of hereditary traits of subjective nerve-processes, but on the rational insight into the objective relations existing between the *abstract* concepts expressed by the subject and predicate. We have seen in the foregoing chapter that sensism cannot account for the abstractness and universality of our universal ideas; our ideas are more than mere 'generic images' of sense-perception. A higher process is involved in their formation. If sensism were correct, evolution could never do more than *fix concrete, individual sense-images* within the tissues of our neural matter; and such images could never account for the immutable, universal, necessary character of our abstract ideas as used in our judgments; much less could they account for the universality and absolute necessity of these principles and axioms under all conditions and circumstances.

Again, as Coffey points out: "The theory proves too much. If it were true that the necessity which characterizes

ideal judgments is a product of accumulated ancestral experience, there is no reason why such necessity should not be found to characterize such judgments as 'fire burns,' 'wood floats,' 'sugar is sweet,' 'day follows night,' etc. — in as much as the connections in these judgments must have been the subject matter of a uniform ancestral experience stretching infinitely backward. Yet such judgments are apprehended as *contingent*, not *absolutely* necessary. On the other hand, the theory does not prove enough; for we recognize an absolute necessity in such judgments as ' $7 + 5 = 3 + 9$,' 'equilateral triangles are equi-angular,' although, as Maher observes, the occasions on which such objects were 'found to be conjoined in experience cannot in the pre-mathematical age have been very frequent.'³

Finally, Spencer teaches that all our knowledge is restricted *to* our internal conscious states. His theory of knowledge is a *trans figured realism*, and all our ideas are but representations and symbols of the unknown and unknowable reality lying beyond the phenomena of sense. Our knowledge thus gives us no insight whatever into physical nature; it is subjectivistic and relativistic. As 'science' this knowledge is useless, if we understand by 'science' a demonstrable understanding of real things and real beings. All we would have is a science of 'symbols' and mental constructions engendered in our mind through the countless repetitions of purely subjective sense-processes, which reveal no more of the reality of things than the chemical symbols reveal the physical properties of the elements for which they stand. Such a theory destroys the

foundations of science as a rational explanation and interpretation of nature.

THE THEORY OF OBJECTIVE EVIDENCE

Neither the associationism of empiricists, nor the formalism of Kantians, nor the evolutionism of Spencerian scientists can give an adequate account of the universality and necessity inherent in the axiomatic truths or first principles. None of these theories pass beyond a subjective and psychological necessity which compels the individual mind to judge that such first principles are universally and necessarily true. That, however, is not sufficient; because we clearly perceive that these principles are not merely true for us, but for all minds and, what is far more important, they apply to all things. The reason why we judge that the subject and predicate of first principles are logically connected with an absolute necessity must lie in something else than an internal, subjective law or form proceeding from the constitution of the mind itself. What, then, forces the intellect to place such an absolute necessity in these judgments? We are here face to face with a primary fact and an ultimate experience present within our consciousness. Because of this, introspection and reflection alone can answer the question. We must give careful attention to what takes place in making such judgments, in order to discover what prompts and compels the intellect to consider such judgments absolutely necessary in their validity. And in doing this we find that the reason or ground for this necessity is seen to lie in the *cogent objective*

evidence of the *logical relation* which exists between the concepts of these judgments, and not in any subjective necessitation arising from the constitution of the mind.

Coffey has given a very lucid and succinct proof in the following words: "When I reflect on my spontaneous assent to such a judgment as that $7 + 5 = 12$, I observe the following facts: (a) that I affirm a necessary identity between predicate and subject; (b) that I affirm the identity *after having seen it intellectually* through comparison of the concept of '12' with the concept of '7 + 5' (c) that I affirm it *because I have seen it*. Moreover, I observe that (d) I see the necessary identity because I see that the concepts *necessarily involve such identity*; that (e) I do not assert it until I see them involve it and then only because I see them involve it; (f) that in order to see them involve it I analyze each concept into its simplest elements: the predicate into a total sum of units (1+1+1+1+1+1+1+1+1+1+1+1) and the subject into two lesser sums (1+1+1+1+1+1+1) and (1+1+1+1+1), whereby I see the former as a whole to be identical with the two latter as its constituent parts. On the one hand I see the parts of a whole; on the other hand I see the whole itself composed of these parts. The identity, therefore, manifests itself to me: I affirm it because it manifests itself to me: it is there objectively revealing itself to my intellect; and this objective manifestation of the *nexus* I call the *objective evidence of the truth of the judgment*. Hence I am conscious that I form such judgments, that I apprehend relations between their constituent concepts, *because I see intuitively* these relations *objectively evident, objectively revealing themselves to me*. Hence I reject as

false the assertion that I establish any such relation *without seeing why I do so*; that I synthesize mental terms or concepts *a priori* and *unconsciously* into a complex representation of which I become conscious as a necessary product or unity, without seeing why it is so. I reject such a doctrine as false because introspection convinces me that I *do* see the reason of my mental assertion of the nexus."⁴

We, therefore, perceive the necessity of such judgments on the grounds of *objective evidence* and *intellectual insight*. The same applies to other first principles: they rest on ultimate concepts whose truth is objectively evident. They can all be reduced to the fundamental concept of 'being.' A 'being' is something 'that is or can be.' Hence, 'Whatever is, is'; and that is identical with 'A being is a being.' Reversely, 'Whatever is not, is not'; and that is the same as 'A not-being is a not-being.' This is the expression of the Principle of Identity. And these concepts are so simple and objectively self-evident that the intellect has an immediate *insight* into the truth of their mutual relation, so that it intuitively perceives that these judgments possess an absolute universality and necessity for both the order of thought and the order of reality. In this principle we merely compare 'being' with itself and 'not-being' with itself and perceive the identity of each with itself.

But when we compare 'being' with 'not-being,' we intuitively behold that the one is not the other. We see the evident truth that 'Being is not not-being,' and that these concepts mutually exclude each other with *absolute necessity*: something 'that is' can never, under any and all conditions, be something 'that is not.' Since 'being' and

'not-being' can never be conceived as identical, but must be universally and necessarily in opposition to each other as contradictories, we express this self-evident truth in the Principle of Contradiction: 'A thing cannot be and not be something at the same time.'

Furthermore, a comparison of 'being' and 'not-being' reveals the evident fact that *there can be no middle thing* between the two. What could such a thing possibly be? Such a middle thing either 'is' or 'is not': if it 'is,' then it is a 'being'; if it 'is not,' then it is a 'not-being.' Consequently, it will be either a 'being' or a 'not-being,' but not a middle thing *between* the two. It certainly cannot be both a 'being' and a 'not-being' at the same time, because that would be impossible in virtue of the Principle of Contradiction as just explained. Hence, it is evident that 'A thing either is or is not,' and that is called the Principle of Excluded Middle.

From these principles to the Principle of Sufficient Reason is but a step. If a thing is a 'being,' it has its being either from itself (i.e., it is un-produced) or from another (i.e., it is produced by this other): in either case it has a *sufficient reason* for its being. If it is not a 'being,' it is so because it has its being neither from itself nor from another: in both cases it is a 'not-being' because it has *no sufficient reason* for its being. Hence, it must be evident that 'every thing must have a sufficient reason for its being'; if this were not so, then there would be no difference between 'being' and 'not-being.'

This last principle leads necessarily to the Principle of Causality. If a thing is a *contingent being*, i.e., if it has not the sufficient reason for its being in itself, it must have it *in*

another; that is to say, this *other* must give being to it. This follows from the Principle of Sufficient Reason. But to 'give being' to another means to 'produce' or 'cause' it. It is, therefore, self-evident that 'every contingent being, i.e., every thing that becomes or happens, must be the effect of a cause.' And so the Principle of Causality is established.

All these principles rest upon the ultimate and absolutely simple concepts of 'being' and 'not-being'; or, to be more exact, upon the one concept of 'being.' Since 'being' is the first and most fundamental concept, these principles based immediately on the concept of 'being' are called in a special sense the *First Principles*. They rest on the fundamental judgment that 'Being is being.' Their universal and necessary truth is thus intuitively perceived to flow from the *objectively* clear and valid concepts of 'being' and 'not-being'; and the intellect does not 'make' their necessary truth, but simply 'perceives' and 'discovers' it. To put their truth into a judgment, then, is nothing more than to express mentally what the intellect perceives to be true objectively. Our conviction as to the absolute necessity and validity of these principles is, therefore, not the result of a blind, instinctive, psychological necessitation due to some hidden law of the mind, but to the objective evidence involved in the concepts and in the logical connection existing between them, so that the intellect is forced by this evidence to assent to their manifest truth in a conscious and intelligent affirmation.

What is the *objective source* of these concepts and principles? The physical world; because our intellect derives its materials from the sensible universe. But how

can the individual, contingent things of the world give rise to principles that are universal, absolutely necessary, immutable, and eternal in truth and validity? The answer is the same as the answer for the truth and validity of universal ideas: they are based on the *abstract essences* of things. Through *abstraction* 'being' is divested of all individuality, contingency, actual existence, space-time conditions, and experience-relations. As such, then, the concept of 'being' and the principles based upon it possess a universality and necessity transcending all contingent existence and are valid for all times, for all places, and for all minds.

Our necessary judgments are thus seen to be objectively valid, and their truth-value is now critically and philosophically vindicated.

SUMMARY OF CHAPTER XV

Judgments consist of ideas. Since ideas represent things, judgments must also apply to reality. Some judgments are considered to be *eternally, immutably, and necessarily true*.

This presents a problem, because judgments, like ideas, are derived from the concrete, individual, and contingent world of objects.

1. *The Problem*. Many judgments express experiential facts, and it is clearly perceived that these facts could be different; they 'happen' to be so, but they 'must' not be so. Other judgments are considered to be eternally, immutably, and *necessarily true*, independent of all experience. Such are the *first principles*.

Whence do these first principles derive their absolute necessity? Why is the intellect *forced* to assent to them? Without the objective truth of these principles science would have no rational basis in reality. Does the logical connection between the subject and predicate of these judgments proceed from our *intellect* or from the *reality* expressed in the judgments?

2. *Empiricists*, like Hume and Mill, find the source of this mental compulsion and necessity in the power of mental *association*; there is merely a subjective, *psychological* necessity for making these judgments. This is false. If it were so, we should experience the same compulsion in every case where facts or events are uniformly and constantly associated in the mind; but this is contrary to all experience. Moreover, this theory of associationism

destroys science, because our knowledge would then be but a purely mental construction which may or may not agree with extra-mental reality.

3. *Kant* considered everything that is universal and necessary in our knowledge to be the result of certain *a priori forms* innate in the mind and antecedent to all experience. Consequently, the absolute necessity of these judgments must come from the *mind alone*. These judgments are the result of a union between the phenomena of sense-intuitions and certain *a priori categories* of the understanding; and these categories are applied to the phenomena according to the workings of an innate, blind law. Our judgments are valid for phenomena, but give us no insight into the reality of the things-in-themselves. This view is destructive of science, because science is convinced that it reaches *real things* outside the mind.

Besides, this necessitation to judge is due to a blind, subjective law of the mind. Science and philosophy, however, demand an intelligent *insight* into the logical connection between subject and predicate, otherwise our certitude has *no rational foundation*; without this insight we would have no real knowledge.

4. *Spencer* and the evolutionists seek the necessity of our judgments in *evolution*. Innumerable associations repeated with countless frequency through long ages produce certain fixed forms of thought, and this accounts for our necessary judgments. This theory cannot explain our *abstract* ideas; because only concrete, individual sense-images could thus be transmitted, not principles with an *absolute* necessity valid under all conditions and

circumstances. Again, all uniform experiences, like 'Fire burns,' etc., should then have the same absolute necessity in our judgments; but that is not the case. Finally, Spencer's 'transfigured realism' destroys the validity of *science*, because reality is considered to be unknown and unknowable.

5. *Objective evidence* alone explains the absolute necessity of these principles. The mind intuitively perceives this necessity of its judgments to proceed from the *objectively evident relation* existing between the subject and predicate of these judgments. The first principles are clearly seen to rest on the concepts of 'being' and 'not-being' and the relation between them. This gives rise to the fundamental Principles of Identity, Contradiction, Excluded Middle, Sufficient Reason, and Causality; and these principles underlie all thought and reality. The mind does not make, but discovers, them.

The *objective source* of these principles lies in the contingent things existing in the physical world. But the mind, through abstraction, divests 'being' of all contingency, actual existence, space-time conditions, and experience-relations; thereby the concept of 'being' and the first principles obtain universality and absolute necessity.

Our necessary judgments are thus seen to be *objectively valid*.

Chapter 16

THE CRITERION OF TRUTH

OUR INVESTIGATION SO FAR HAS SHOWN THAT WE HAVE A knowledge of reality. The senses present reality to the mind through the medium of percepts. The intellect, then, fashions concepts or ideas which are representations of reality in an abstract and universal manner. Mere percepts and concepts do not as yet constitute knowledge; they are the raw materials, rather than the finished product, of knowledge. We have knowledge when we affirm or deny something of something; and that takes place in the *interpretative judgment*. A judgment is always a mental pronouncement about reality in some form or other, and this pronouncement represents the actual condition of reality as it is in itself. Judgments, therefore, possess a *truth-claim*.

Unfortunately, however, our judgments are not always true; quite frequently we discover that they are erroneous. Now what constitutes *truth* and *error*? And how can we *discriminate* between true and erroneous judgments? What is the test or *criterion* of truth? And what is the *ultimate criterion* for distinguishing truth from error? These are important questions that will now have to be answered.

TRUTH AND ERROR

An *idea* is the intellectual representation of a thing. Due to the limited power and capacity of our intellect, we are incapable of grasping the full reality of an object within the content of a single idea. In consequence of this, the intellect turns its attention first to this, then to that property or attribute, and makes a separate concept for each one. In nature, the thing is actually undivided and one, but potentially divisible and many; in the intellect, the concepts of the thing are actually divided and many, but potentially undivided and one. The intellect recognizes this fact. None of these ideas represents the full reality, but each represents an aspect, a phase, a portion of it. The *material* object of the idea is the total object in all its properties and attributes; the *formal* object of the idea is the thing in its single property or attribute, in so far as it is represented by the single idea. In order that the idea be a true representation of the thing, it must agree with its formal object. While the idea is thus seen to be a piecemeal representation, it is *true as far as it goes*: to be incomplete is not the same as to be incorrect.

Just as the intellect acquires a more or less complete grasp of a thing by means of a *mental division* of its reality into a number of concepts, so it subsequently makes a mental synthesis of the object and its attributes in the *judgment*. What was divided in the process of abstraction again becomes united in the act of judgment: the attribute (predicate) is referred back to the thing (subject), as when we say that 'the rose is red,' 'the rose is beautiful,' 'the rose

is fragrant,' 'the rose is fresh.' It will be noted that the subject ('rose') stands for the thing in a general way, while the predicate ('red,' 'beautiful,' 'fragrant,' 'fresh') stands for the particular attribute which belongs to the thing and which was recognized as belonging to the thing in its *objective existence*. Thus, what the judgment pronounces of its ideas is meant to be pronounced of the reality itself, because ideas are (partial, but true) representations of objective reality. Every judgment implicitly expresses a correspondence between the thing as it is in itself and as it exists ideally in my intellect, although explicitly the judgment merely pronounces an identity between the predicate-concept and the subject-concept. Such is the nature of the *affirmative* judgment.

The negative judgment is similar in import. Here I take an attribute *not* found in the thing and *deny* its presence in the thing. Judgmentally, I exclude the predicate-concept from the subject-concept; and in doing this I mean to assert that the reality signified by the predicate is lacking in the thing signified by the subject. Again I express a conformity between the reality as it exists in the real order of nature and as it exists in the ideal order of my mind. When I say that 'The rose is not blue,' 'the rose is not a cabbage,' 'the rose is not dead,' I pronounce the non-identity between subject and predicate as valid in the logical and ontological domain. In the affirmative and negative judgments, therefore, I claim that there exists an agreement between thought and thing.

Therein lies *truth or error*. If I judge that an attribute belongs to a thing, and it actually does, then I have truth;

so, too, if I judge that an attribute does not belong to a thing, and it actually does not, I have truth. But if I judge that an attribute belongs to it, while it actually does not, or if I judge that an attribute does not belong to it, while it actually does, I have error. For example, I state that 'The rose is red,' 'the rose is not yellow'; if this is so as stated, my judgment is true. If, however, I were to state that 'The rose is yellow,' 'the rose is not red,' while as a matter of fact it is red and not yellow, my judgment would be erroneous.

Truth and error, then, reside formally in the judgment, and not in the ideas taken alone for themselves. Truth must, therefore, be defined as the *conformity of judgment to reality*; and *error*, as the *disconformity of judgment to reality*. Common usage and reflective analysis agree in considering truth to be an agreement between mind and thing, and error to be its opposite. Any other definition would be confusing and unwarranted, unless it consist merely in a difference of wording.

CRITERION OF TRUTH, MOTIVE OF CERTITUDE

Since knowledge is useless, if it does not agree with reality, i.e., if it is not true, it is of prime importance to know whether we possess a 'criterion' of truth. By criterion in general we understand a means or rule of discrimination, whereby we can distinguish one thing from another. A *criterion of truth* is a rule, or norm, or standard, or *test by which we distinguish true judgments from those which are false*. The application of this norm or test to a judgment will then enable us to decide whether the judgment is true or

false. Since the judgment is a natural mental process, the criterion of truth must be a *natural* norm or test, well within the reach of every individual; and since the judgment is an intellectual process, the criterion of truth must be discoverable by the *intellect*. If there are a number of criteria, there must be one which is final and fundamental and beyond which there is no appeal; because, if every criterion demanded another criterion to establish its worth and validity, we would have an infinite regress and would never be able to come to a definite decision concerning the truth or error of a particular judgment. This final and fundamental criterion, beyond which there is no appeal, is the *ultimate criterion of truth*.

That such a criterion is necessary, must be obvious. Things in nature are at times extremely complicated in their reality. To obtain a more or less complete knowledge of them is a difficult and laborious task, depending on a multitude of conditions relative to the thing itself, to the organs of sense perceiving them, and to the intellect fashioning its concepts and judgments. That error can and does occur in our judgments is too clear to be disputed. Without some criterion of truth we could never detect error and distinguish it from truth; it would then be impossible to correct or change our judgment once it is made. As a result, our knowledge of reality might in many instances be totally at variance with the objective status of things, and we would be completely unaware of the fact; indeed, without such a criterion it would be absolutely impossible for us to become aware of any error in our judgments.

That we actually possess a criterion of truth, must be obvious. This is proved by the very fact that we *change* and *correct* our judgments after having become conscious of error. We could not correct an error, were we not conscious of error; and we could not be conscious of error, if we were not able to distinguish it from truth; and we could not distinguish it from truth, if there were no means or rule or test enabling us to discover both and discriminate them. The *fact of discrimination*, then, proves that we possess a criterion of truth and actually use it. Whoever acknowledges that we have natural certitude in our judgments thereby admits the existence of a natural criterion of truth; and only a universal skeptic will deny that we have certitude.

Certitude is that state of the mind in which the mind gives a *firm assent* to a judgment *without fear of error, due to recognized valid reasons*. The absence of fear is the 'negative' factor in certitude, and all judgments of whose truth we are convinced are alike in this respect. The valid reasons are the 'positive' factor, and according to their convincing strength we distinguish between *moral, physical, and metaphysical certitude* (see Chapter 2). That we have these different degrees of certitude in our judgments is clear from our internal experience. *Moral certitude* is based on the customary action of human beings, and exceptions to the law are recognized as *physically possible*; as when we are sure that 'Parents love their children.' *Physical certitude* rests on the physical laws of the world, and exceptions here are impossible in the ordinary course of nature, though possible to the Creator;

as when we are convinced that 'Iron will sink in water.' *Metaphysical certitude* has its foundation in the metaphysical laws of being, so that an exception is intrinsically impossible, because it would involve an internal contradiction; such is the absolute certainty of ideal principles, as 'The whole is greater than any of its parts.'

Whenever we are certain in such judgments, we are conscious of a motive of certitude. The motive of certitude is the ground which determines us to assent with firmness to a judgment as true without fear of its contradictory being true. We never assent to a judgment without some positive reason which we consider a good or valid reason. Valid reasons are the 'motive' of certitude. If we 'doubt' the truth of a judgment, it is because we realize that we either have no reason or motive for its acceptance or because the reasons or motives are about equally balanced for and against its acceptance. If we have a 'probable' judgment, we are conscious that we accept the judgment, but with fear of its contradictory, because the reason or motive for our assent is not of such a nature as to exclude fear of error. Our conscious experience is a daily and hourly witness to these different states of mind, and the mere mention of this fact should be sufficient to prove the truth of the statement that certitude is grounded on the motive of valid reasons.

We distinguish between *subjective* and *objective* certitude. The former consists in the mere *firmness* of our assent, and it does not exclude error in our judgment; it does, however, exclude the *fear* of error, considered solely as a subjective state of the mind itself. Objective certitude

consists in the *reasons* contained in the *terms of the judgment*, in virtue of which the judgment is considered to be a true representation of reality. Our judgment being an intellectual act, the grounds or motives, which determine the intellect to give a firm assent to it as true, must possess an 'intellectual' character; that is, they must be such that they appeal to the intellect within the judgment itself. Now, the intellectual element in the judgment which appeals to the intellect is precisely the *truth-value* of the judgment as an interpretation of reality; hence, the same reasons which determine the truth of the judgment also determine the certitude of the intellectual assent. The criterion of truth and the motive of certitude are thus seen to be *conceptually different*, but *objectively identical*. It follows from the very nature of the intellect as a 'cognitive' faculty that the element which constitutes the test or criterion of truth will also be the motive *why* the intellect gives a firm assent to the truth. And just as we must have an ultimate criterion of truth, beyond which there is no appeal, so, too, there must be an *ultimate motive* of certitude which is the foundation for all secondary motives. because at bottom the criterion of truth and the motive of certitude are objectively identical.

The question before us, then, is this: *What is the ultimate criterion of truth?* The answer to that question will also be the answer to the further question as to what constitutes the ultimate motive of certitude, since the 'reasons' of the truth of the judgment are also the 'motive' for our intellectual certitude that the judgment is true. And here again, as in all problems which reach down into the roots of knowledge, a strict demonstration is impossible, because

primary facts are a matter of ultimate *experience*. The only course open to us is to scrutinize our mental acts closely and carefully and observe just what the intellect uses as its criterion of truth and what is its motive of certitude, when it gives its firm assent to a judgment. Doing this, we will see that this criterion and motive is the *objective evidence of reality*.

NATURE OF OBJECTIVE EVIDENCE

By *objective evidence* we understand that characteristic of reality whereby it becomes *objectively manifest to the perceiving faculty*. What the luminosity of a shining body is to the eye, making it clearly visible, that the evidence of reality is for the mind: it makes reality cognitively clear and intelligibly apparent to the intellect. In virtue of this objective evidence or clear self-revelation of reality in the presence of the intellect, the intellect is capable of forming a judgment which is a correct interpretation of this reality as it exists in its objective being. The intellect sees the reason or ground for its judgment in the reality as it reveals or manifests itself to the mind, and it makes this judgment *precisely because the reality* is thus *seen* to reveal or manifest itself with such clarity. The reason or ground for accepting this judgment as true and the motive for assenting to it with the firmness of certitude have their source, not in the judging subject, but in the evidence of the *object*; in other words, it is the *objective evidence* of reality which determines the judging subject to interpret this

reality in the way it does and thereby makes the judgment to be true and certain.

Objective evidence is in relation to the truth and certitude of the judgment what the cause is to its effect. There are various *kinds of evidence*, according to the manner in which the objective truth of reality becomes apparent to the mind. Objective evidence will be either 'internal' or 'external.'

Internal evidence exists, when the ground for our judgment is clearly perceived to lie *in the reality* affirmed by the judgments. Such, for example, would be the judgments, 'The sun is shining this afternoon,' ' $2 + 2 = 4$,' 'a circle is round.' Internal objective evidence will be *immediate*, when the reality interpreted in the judgment is directly presented either to the intellect or to the senses. That ' $2 + 2 = 4$ ' and that 'A circle is round' and that 'The whole is greater than any of its parts,' are true judgments based on the evidence of the relations existing between these concepts as immediately perceived by the intellect in contemplating them. And that 'The sun is shining' and that 'This paper is white,' are true judgments based on the immediate evidence of my experience as revealed through my senses. In both cases reality becomes evident to me by being directly presented to my faculty. On the other hand, internal objective evidence will be *mediate*, when the reality manifests itself to my mind, not by means of a direct presentation, but by means of a *process of reasoning* which leads ultimately to reality which is immediately evident. For instance, when I ride over the highway and see the whole countryside drenched with water, I have mediate evidence

that 'It rained.' I did not see the rain fall, but it is evident that rain must have fallen; had I seen it fall, I would have immediate evidence of the fact. So, too, the judgment that '15,486 is evenly divisible by 5162' is only mediately evident to most people, until they make the actual division. When a ballistic expert proves that a particular bullet was discharged from a particular gun, it is mediate evidence; had he seen the gun fired, it would be immediate evidence.

External evidence exists, when the ground for our judgment does not lie in the reality itself affirmed by the judgment, but in some *other reality outside it*, and this external reason is clearly perceived to be of such a nature as to guarantee the truth of the judgment and to exclude the fear of error from our assent. This may be twofold: the evidence of *authority* and the evidence of the *imprudence of doubt*. The former rests on the evidence of the motives of *credibility*, in virtue of which the intellect is convinced that the witness deserves credence because of his knowledge and veracity. I may not have been present at the battle of the Argonne; but when I consider the number and character of the many witnesses who claim to have participated in this battle, I have reliable evidence that such an event actually occurred. Our knowledge of history is thus based to a great extent on the external evidence of authority. And so is much of our knowledge of persons, localities, and scientific discoveries; most of these things we accept on the authority of others who witnessed them and are trustworthy in their testimony. This is the rational basis of 'belief.' The evidence of the *imprudence of doubt* is such that it is not sufficient to compel our assent, but is clearly

perceived to be sufficient to *exclude all unreasonable doubt*. In this case the absence of compulsion is frequently due to our lack of insight in consequence of the limited character of our personal faculties. For me to doubt the truth of some abstruse and complicated mathematical proof, simply because I am not capable of following the argument, would be unreasonable; provided, of course, that mathematicians of repute all agree as to its truth and validity. Similarly, it would be unreasonable to doubt that the one who claims to be my mother is really my parent, even though I cannot adduce any positive proof to substantiate the fact. Or, it would be imprudent on my part to doubt the reality of an extra-Ego world, merely because some obscurities can be found in the theory of direct and immediate sense-perception.

Such is the nature of objective evidence. When we say that the criterion of truth and the motive of certitude is 'objective evidence,' we mean the objective evidence of reality (internal and external evidence) revealing itself to the mind. But when we speak of the 'ultimate' criterion of truth and the 'ultimate' motive of certitude, we claim that both consist in *internal, immediate, objective evidence*. 'External' and 'mediate' evidence are, of course, sufficient to give us certitude, but only because they presuppose internal, immediate evidence to support them. It will be necessary, then, to show, first, that objective evidence in general constitutes our criterion of truth and motive of certitude, and, second, that internal, immediate evidence is our 'ultimate' criterion and 'ultimate' motive, giving validity in the last instance to all truths and *all* certitude.

EVIDENCE THE CRITERION OF TRUTH

In proposing this proof, we must bear in mind that a strict demonstration is impossible. Primary facts cannot be demonstrated, but are shown to be true by an appeal to fundamental experience and reflection; what can be shown to be true by a mere exposition of the facts needs no strict demonstration. I cannot demonstrate, for instance, that I actually can see; the fact of seeing is its own proof. Similarly, I cannot 'demonstrate' that evidence is the criterion of truth, because such a demonstration would require the criterion of truth to prove that it is true: that means that I would prove a thing by itself, which would be a begging of the question. Nor can I disprove with a strict demonstration that evidence is not the criterion of truth, because in that case I would have to use evidence to disprove evidence: and that would again amount to a begging of the question. It is only by seeing what actually induces the intellect to accept judgments as true and what actually determines it to give a firm assent to the judgments as true, that I can decide what constitutes this criterion and motive. Now, *experience and reflection* clearly show that as a matter of *fact* objective evidence is our criterion of truth and our motive of certitude.

Why do we affirm some predicates of subjects, while we deny other predicates of these same subjects? Because we are convinced that some predicates really *belong* to these subjects and others *do not belong* to them. We certainly do not act arbitrarily in this matter of applying predicates to subjects. Frequently we would prefer to make a judgment

one way rather than the other; but we cannot honestly do so, because we know that such a judgment would not be true. This shows plainly that the reason why we consider judgments to be true and assent to them with certitude does not proceed primarily from the mind itself. Why is this? Because the intellect needs a *ground or reason outside itself* in order to make a judgment one way rather than the other. If our intellect had the ground or reason for its judgments solely in itself, then our judgments would have no objective value and would not be an interpretation of the objective reality designated by the subject and predicate.

Our judgments, however, are clearly perceived to be an interpretation of extra-mental *things, objects, realities*; in other words, judgments represent a conformity of our intellect to objective reality, and our intellect judges this reality to be so-and-so or not-so-and-so because it is the 'thing' which influences the intellect to judge about it as it does. And *why* and *how* does the thing influence and determine our intellect in judgment? Because the thing *presents itself* with such clarity to the contemplating intellect that the latter plainly sees that the reality of the thing is so-and-so or not-so-and-so and judges accordingly. It is the thing itself which produces in the mind a *clear insight* into its objective reality as being precisely 'this' and 'not that.' But this characteristic of objective reality, whereby it presents itself with unquestionable clarity to the contemplating intellect, is what we understand by 'objective evidence.' In making a judgment, then, which corresponds to this evident reality, the intellect *recognizes* the fact that

the judgment is *true* and cannot be otherwise than true; and that is also the ground or reason for its certitude about the truth of the judgment. Consequently, objective evidence is the criterion of truth and the motive of certitude in our judgments.

A consideration of the various *types of truths* confirms this general analysis. In sense-perception the criterion and motive is the clear *presentation* of external objects. In consciousness it is the immediate *union* between consciousness and the presented internal fact or event. In first principles or ideal judgments, as we have seen in the preceding chapter, it is the objective evidence of the *identity* or *non-identity* existing between the subject and predicate manifesting itself in the concepts. In mediate judgments, as we have them in discursive reasoning, it is the obvious *identity or non-identity* of two objective concepts with a third, based on the Principles of Contradiction and Identity. In judgments made on the authority of others, it is the clearly perceived *moral impossibility* of error due to the knowledge and veracity of the witnesses relating their immediate experience. In judgments resting on the imprudence of doubt, it is the objective clarity of the *facts* which enables the intellect to see that doubt would be unreasonable under the circumstances.

All these types have this in common that they induce the intellect to adhere to them with an assent of certitude, and the reason for this is that the presented and interpreted *reality* contained in them manifests itself to the intellect with a *clarity* that excludes doubt as to its existence and

nature. That, however, is the 'objective evidence' of reality revealing itself to the mind. If this were not so, the only alternative left would be that the *intellect makes* these judgments true: but in that case it would be inconceivable how any judgment could ever be *false*.

We obtain the same result when we compare the attitude of the mind in certitude, doubt, and opinion. When is the mind in 'doubt'? When it is uncertain whether the predicate really belongs to the subject and should be identified with it. But why is it uncertain? If the reason or ground for identifying the predicate with the subject resided primarily in the mind, there should be no difficulty in identifying or not identifying the predicate with the subject and thereby attaining truth and certitude, because in that case the judgment would *always* correspond with the mind, and there should never be any state of doubt. Doubt, as experience and reflection clearly show, arises out of the inability of the intellect to discover whether the aspect of reality contained in the predicate actually belongs to the object represented by the subject. And this is due to the fact that the reality itself is not clearly manifested to the intellect; in other words, it has insufficient 'objective evidence.' When we have an *opinion*, we actually judge that something is 'so-and-so' or 'not-so-and-so'; but we are not free from the fear of error in this judgment. Why? Because we are *not sure* that the thing is *really* as it is judged to be. And why are we not sure? Because the *reality itself is not clear* to the intellect; if it were, there would be neither doubt nor opinion, but certitude, in the mind. It is, therefore, the lack of 'objective evidence' which creates the

state of doubt and opinion in the mind; and, reversely, it is the 'objective evidence' of reality which guarantees the truth of the judgment and produces the firm assent of certitude.

Our analysis of truth and certitude thus shows that objective evidence of reality, or reality itself as clearly manifested to the intellect, is the criterion of truth and the motive of our certitude. Without it, the intellect must remain in doubt or, at the very best, can only form a probable opinion, and then the fear of error will always be present.

THE ULTIMATE CRITERION AND MOTIVE

Objective evidence in general is the criterion of truth and the motive of certitude. But not all evidence is equally valuable in establishing the truth of a judgment and in producing the firm assent of certitude. For instance, the external evidence of human authority and of the mere imprudence of doubt is the weakest kind of evidence, because here reality manifests itself to the intellect only indirectly and secondarily. Such evidence always rests on some other evidence which is direct and primary. But it is obvious that we cannot refer one sort of evidence back to another indefinitely, otherwise we would become involved in an 'infinite regress,' and thus nothing would ever be sufficiently evident to give us truth and certitude in our judgments. There must be some criterion of truth and motive of certitude beyond which there is no need of appeal and for which there is no need of further evidence; in other

words, there must exist an *ultimate criterion of truth* which is also the ultimate motive of certitude. What is it? It is *internal, immediate, objective evidence*, or, in one word, *self-evidence*.

That we cannot give a strict demonstration for this claim, has been pointed out above, when we spoke of evidence in general. We can only make an appeal to intelligence and to primary experience. Now, that evidence will have to be the 'ultimate' criterion of truth and the 'ultimate' motive of certitude which is of such a nature that there can be *no possibility of doubt or error* in the mind as to the conformity of its judgment to the reality it interprets. In order that there be no possibility of doubt, the reality must be so clear and luminous before the intellect that there can be no danger of error in its judgment. And in order that there be no possibility of *error*, the reality must again be so clear and luminous that the intellect must see that the reality is actually 'so-and-so' and cannot be otherwise. But this condition is fulfilled only when the reality expressed in our judgments is *self-evident*; that is, when reality manifests itself to the intellect with an evidence which is 'internal' and 'immediate.'

Introspection and experience show this plainly. Let us glance at 'external' evidence. Such evidence may be based either on authority or on the imprudence of doubt. *Authority* cannot be the ultimate criterion of truth and motive of certitude, for the simple reason that it does not exclude the possibility of doubt. The person on whose authority I accept the truth might be mistaken. And if he cannot be mistaken, it is only because *he* has had

‘immediate’ and ‘internal’ evidence of the truth. After all, then, I am not relying on my evidence, nor on his word of authority, but on the immediate and internal evidence of the reality manifested to *him*; and that implies that the external evidence of authority must be based ultimately on internal, immediate evidence. The same is true of the evidence of the *imprudence of doubt*. What is evident here to me is that doubt is ‘imprudent’; therefore I reject it as unreasonable, and by an effect of the will I induce the intellect to give a firm assent to the judgment. Such an assent does not exclude the possibility of doubt and error; that possibility always remains in judgments of this kind. Consequently, the evidence which merely shows that doubt is imprudent cannot be the ‘ultimate’ criterion, because the ultimate criterion must exclude the very *possibility* of doubt and error.

And now let us consider *mediate* internal evidence. Such evidence must always have its foundation in ‘immediate’ evidence. The very fact that it is only ‘mediate’ shows clearly that it refers to other evidence beyond itself; if it were not so, it would itself be ‘immediate.’ We have mediate evidence in the various processes of reasoning. But why do we ‘reason’ to the truth of the conclusion of an argumentation, except for the fact that this conclusion must be *proved* by the evidence contained in the premises from which it is drawn? And if these premises are not self-evident, they must also be proved by other premises which are immediately evident; and if the latter are not self-evident we must continue proving premises until we finally arrive at premises which need no proof, because they are

self-evident. Hence, mediate evidence cannot be the 'ultimate' criterion of truth and the 'ultimate' motive of certitude, because it always presupposes immediate, internal evidence to guarantee its own truth.

The only sort of evidence left, then, as the ultimate criterion and ultimate motive, is the immediate, internal, objective evidence, or the *self-evidence*, of reality manifesting itself to the intellect.

EXPERIENCE SHOWS CONCLUSIVELY THAT ALL KNOWLEDGE IS BASED ultimately on the self-evidence of reality. The structure of our common, scientific, and philosophic knowledge is a very complex thing, built up gradually and laboriously from previous judgments that have been recognized as true. But if we trace our knowledge back to its origin, we will find that it is based on immediate sense-perception, immediate consciousness, and immediate insight into first principles. And if we examine the truths acquired from these sources, we will observe that they *reveal reality* to us in such a manner that the intellect *clearly perceives* that this reality is so *self-evident* as to exclude the very possibility of doubt and error. And this self-evidence of reality is seen by the intellect to be the final and ultimate ground for its judgments and certitude. We have but to consider that all our knowledge derives its validity from the necessary and universal truth of a few first principles, in order to see for ourselves that self-evidence is the ultimate criterion and motive. Such principles are, as we have seen in the foregoing chapter, the Principles of Identity, Contradiction,

Excluded Middle, Sufficient Reason, and Causality. They underlie all science and all knowledge. A little reflection will convince us of this.

There are certain general principles which are the foundation of science and knowledge in all their ramifications. Such are the judgments, 'The whole is greater than any of its parts,' 'two things identical with a third are identical with each other,' 'what is true of a logical whole must be true of the logical parts of that whole,' ' $2 + 2 = 4$,' etc. Once the meaning of these concepts is understood, the necessary truth of these judgments becomes self-evident and needs no demonstration. Take, for example, the judgment that 'The whole is greater than any of its parts.' By 'whole' I mean 'a sum of constituent units' and by 'part' I mean 'one of a number of units constituting a sum.' Since the 'whole' is thus seen to be a 'sum,' and a 'part' is seen to be one of the 'units' of this sum, my understanding of these concepts reveals to me the self-evident truth *beyond the possibility of doubt or error* that 'The whole must be greater than any of its parts.' Because, if this were not so, the 'whole' would not be a 'whole' and the 'part' would not be a 'part'; and that would involve the contradiction that 'being' would not be 'being' but would be identical with 'not-being.' Thus, the truth of this judgment is seen to run through the Principles of Contradiction and Identity down to the fundamental and absolutely simple concepts of 'being' and 'not-being.' If there could be a possibility of doubt and error in this, then truth and certitude is simply impossible of attainment.

And so it is with all principles and all knowledge, whether of the existential or of the ideal order: they rest on the self-evident Principles of Identity, Contradiction, Excluded Middle, Sufficient Reason, and Causality. In other words, the ultimate criterion of all truth and the ultimate motive of all certitude lie in the *self-evidence* (internal, immediate, objective evidence) *of reality* as it manifests itself to the intellect and is recognized by the intellect as such.

But if this is so, how is error possible? It would seem that error should never occur in our judgments. Error, however, is an undeniable fact. What, then, is the cause of error?

THE CAUSES OF ERROR

We have seen above wherein error consists. It is the non-correspondence or disconformity of the intellect with the thing. Just as truth is in the judgment, so is error. It always involves the *affirmation of what is not true and the denial of what is true*. Since truth is the result of evidence, error must have its origin in the lack of *real* and in the presence of *apparent* evidence.

Reality as such cannot be false; it reveals itself to the mind as it is. Error, therefore cannot come from reality itself. But if it cannot come from reality, it must have its origin *in the mind*. Now, the mind as such tends toward truth and not toward error; the mind, therefore, is not inherently false. And yet it is evident that the mind does actually assent to judgments which are erroneous. How is this possible? The fact is simply that error is in the mind,

but does not proceed *from* the mind. It has its cause in the *will*. This needs explanation.

We have seen that in the presence of 'self-evident' reality there is no possibility of doubt or error for the intellect. Unfortunately, however, reality is not always self-evident. Conditions are often such that the reality cannot reveal itself with self-evident clarity to the mind. This clarity is frequently obscured, partly through the *complexity of reality* itself, partly through the *limitations and imperfections* inherent in the organs which serve the intellect and furnish it with the materials necessary for knowledge. In consequence of such conditions reality will sometimes appear to the mind other than it really is. In many instances the mind *could* discover what the reality 'really is' by means of a close and exact analysis of all the circumstances, but it is here that the influence of the will enters as a deciding factor and induces the intellect to give its assent to a judgment for which it has no *sufficient evidence*.

But why should the will urge the intellect to assent to a judgment for which there is insufficient evidence? At times the *exigencies of life* and the *need of immediate action* require a definite decision and a definite acceptance of one side of a question. The will then compels the intellect to be satisfied with the limited evidence at hand and to give its firm assent. That error is not only possible, but probable and frequently actual, in such circumstances, is but natural. Again, in many cases, the only evidence available under existing conditions of time, place, educational facilities, etc., is *mediate or external*. Rather than refrain from a decision

entirely, the will influences the intellect to give its assent. The motives are really *sufficient* for the ordinary purposes of ordinary life; since, however, they do not rest on the 'self-evidence' of reality, they do not exclude all possibility of error, and the intellect may thus pass a judgment which is a faulty interpretation of reality.

In very many instances the will is swayed by *partisanship and prejudice*. Likes and dislikes, loves and hates, pleasure and pain strongly influence the will in its decisions and these decisions exert a corresponding influence on the judgments of the intellect. There are even such things as *scientific prejudices*. Since the reality of the universe is so vast and complex, preventing a complete unification and systematization in the limited mind of man, various hypotheses and theories obtain plausibility in the course of time among scientists. All scientists are human, and absolute impartiality in the search for truth is a morally unattainable ideal. Eager to substantiate their own views, they unconsciously favor all partial evidence which seems to prove their hypothesis or theory. They frequently overlook real contrary evidence. Here indeed 'the wish is father to the thought,' and error is the result. That religious prejudices frequently color judgments and lead to errors, needs hardly be mentioned.

Emotional instability and the desire to *shirk* protracted *labor* are also prolific causes of error. We want short-cuts to results. Our hectic haste of living, our love of ease and indolence, our proneness to distractions of all kinds make us impatient of the drudgery of long and arduous study and research, and that hinders the intellect from bending all its

energies to the proper sifting of evidence. All this, added to faulty methods and defective information in our preliminary education, has the tendency to make us slipshod in our search for truth. Many errors could be avoided through greater care and effort in our thinking.

From the above analysis of the causes and occasions of error, we see that error is not an inherent characteristic either of reality or of intellect; it is the result of the determining influence of our will. Error as such is *incidental* and *accidental* to judgments; proper attention to the objective evidence of reality makes it avoidable. And this shows that our judgments are *essentially valid* as true interpretations of reality.

SUMMARY OF CHAPTER XVI

A judgment is always a mental pronouncement about reality; as such, it possesses a truth-claim. What constitutes truth and error? How can we discriminate between them? What is the criterion of truth?

1. *Truth and Error.* Judgments refer to reality. Therein lies truth or error. If judgments correctly interpret reality, they are true; if incorrectly, they are false. Truth, therefore, is the *conformity of judgment to reality*; error, the *disconformity of judgment to reality*.

2. *Criterion of Truth; Motive of Certitude.* A criterion of truth is the rule or test by which we distinguish true judgments from false; the final criterion, beyond which there is no appeal, is the *ultimate* criterion. Such a criterion is necessary, otherwise we could not distinguish truth from error. That we possess a criterion, is clear from the fact that we correct erroneous judgments.

Certitude is that state of the mind in which it gives a firm assent to a judgment *without fear of error*, due to recognized valid reasons. The *motive* of certitude is the ground or reason which determines us to assent with firmness to a judgment as true; it is the recognized *truth-value* of the judgment. The same reasons which determine the truth of the judgment determine also the certitude of the assent; hence, the criterion of truth and the motive of certitude are objectively identical, though conceptually different. The criterion of truth is *objective evidence*.

3. *Nature of Objective Evidence.* It is that characteristic of reality whereby it becomes *objectively manifest to the perceiving faculty*. There are various kinds of objective evidence.

Internal evidence exists, when the ground for our judgment is clearly perceived to *lie in the reality* affirmed by the judgment. If this interpreted reality is directly presented to the intellect or the senses, this evidence is *immediate*; otherwise it is *mediate*. *External* evidence exists, when the ground for our judgment lies, not in the reality itself affirmed by the judgment, but in some other reality *outside* it. Such is the evidence of *authority* and of the *imprudence of doubt*. Objective evidence, whether internal or external, is the criterion of truth and the motive of certitude; but the *ultimate* criterion and the *ultimate* motive is internal, immediate evidence, or self-evidence.

4. *Evidence the Criterion of Truth.* Experience and reflection prove this. We do not arbitrarily apply predicates to subjects and consider such judgments true. The intellect needs a ground or reason outside itself, because judgments are clearly perceived to be interpretations of extra-mental *reality*. Hence, the clear presentation of reality is the ground for considering judgments to be true and worthy of a firm assent; but that is the 'objective evidence' of reality. All *types* of truths reveal this same fact. The difference between the attitudes of the intellect in *certitude*, *doubt*, and *opinion* is due to the difference of reality in its self-revelation to the mind.

5. *Ultimate Criterion and Motive.* The ultimate criterion and ultimate motive must be such as to exclude the

possibility of doubt or error. To do this, reality must be *self-evident*; the 'external' evidence of authority and of the imprudence of doubt does not exclude the possibility of doubt and error, and 'mediate' always rests on 'immediate' evidence. *Experience* proves that all knowledge derives its validity from a few fundamental principles which are self-evident, because they are based on the self—evident concepts of 'being' and 'not—being.

6. *The Causes of Error.* Error is not caused by reality, because reality reveals itself as it is; nor by the mind directly, because it tends toward truth. Error is the result of the influence of the *will* on the intellect, inducing the latter to assent to a judgment without sufficient objective evidence on the part of reality. The *factors* which move the will in this are manifold: the complexity of reality, imperfections in the organs, necessity of action, partisanship and prejudice, emotional instability and the desire to shirk protracted labor.

Error is thus *incidental* and *accidental*. Our judgments are, therefore, essentially valid as true interpretations of reality.

Chapter 17

FALSE CRITERIA OF TRUTH

IN THEIR ENDEAVOR TO DISCOVER A CRITERION OF TRUTH, philosophers advance various theories. Quite naturally, their views are influenced to a very great extent, if not completely, by their general theory of knowledge. Scientists as a rule, when engaged in the practical work of research, submit to the guidance of the objective evidence of reality; they demand that every hypothesis and discovery be tested by 'experiment,' and that is nothing less nor more than an appeal to objective evidence. But even scientists, when they enter the speculative field of philosophy, at times advocate theories at variance with their practical views. Professional philosophers, of course, attempt the solution of the problem of truth and certitude by reasoning from the principles of knowledge in general. As a result, diverse theories have arisen, and these now demand our attention. Some criteria are *intellectual*, and some are *non-intellectual*, in character. By showing their inadequacy, 'objective evidence' as the criterion of truth will be indirectly confirmed.

DESCARTES, MALEBRANCHE, ROSMINI

According to *Descartes* the things of which we have a *clear* and *distinct idea* are true. He accepted his own existence as true, because he had a 'clear' and 'distinct' idea of it. This, then, became for him the criterion of truth.

Now, the 'clearness' and 'distinctness' of our ideas can be taken subjectively and objectively. Taken *subjectively*, it means that the idea as a subjective product of the intellect is clearly and distinctly conceived; it is clear and distinct to the intellect. But this does not give us a guarantee that this idea corresponds to reality, and that the reality represented in the idea actually exists. I can have, for instance, a very clear and distinct idea of a centaur or a fairy or a mythological deity; but does that mean that such beings exist? To distinguish between such beings and 'real' beings I need some criterion different from the subjectively clear and distinct ideas of them. Taken *objectively*, it means that the idea is clear and distinct as an interpretative representation of reality; the idea is such, because the *reality itself* is clear and distinct before the mind. In that case, however, we have immediate, objective evidence of reality as the criterion of truth, and not the mere clearness and distinctness of the idea as such. Descartes, however, took this criterion in a subjective sense, because he maintained that the external world cannot be presented to the spiritual mind. As such, his criterion of a 'clear and distinct idea' is inadequate, since it can never show us whether our judgments agree with reality.

Malebranche, accepting Descartes' view that we cannot acquire a direct knowledge of the material world through sense-perception, tried to explain this knowledge by

assuming that we have an *intuition* of reality *in the Mind of God*: we see all things in God. The Mind of God, then, is our criterion of truth. This, of course, is contrary to experience. We have absolutely no consciousness of an intuition of God in any form. And if we had, *error* would be utterly *impossible*, otherwise God Himself would have erroneous ideas of things.

Though *Rosmini* (1797—1855) differs from Malebranche in details, fundamentally his view is the same. We have a direct intuition of *Being* in its transcendental ideality, and this innate concept or intuition makes the soul intelligent. Real knowledge, therefore, is derived from this intuition of Ideal Being. The objection against Malebranche's view applies here also: we have no consciousness of such an intuition, and error would be unaccountable, because impossible.

The theories of Malebranche and Rosmini are a form of *ontologism*. *Gioberti* (1801—1852) maintained a similar doctrine.

THE THEORY OF COHERENCE

Idealistic monism of the Hegelian type does not accept the view that, in order to be true, judgments must correspond with extra-mental reality. There is a simple reason for this: since thought and thing, ideal and real, Ego and non-Ego, are fundamentally identical in the Absolute, there exists no extra-mental reality with which judgments could correspond. The truth of a judgment, then, must be its *coherence*, or consistency, with the *whole system of*

knowledge previously recognized as true. When the whole system of accepted judgments is true, any particular judgment in harmony with it will be true; otherwise it will be false. After all, reality is reality for us only in so far as it is known by us; and this knowledge is expressed by us in a systematic body of judgments acknowledged to be a correct interpretation of our experiences.

This criterion of truth, namely the *coherence* of a particular judgment with our general system of knowledge, is *inadequate* and therefore of little value for judging the truth of our mental pronouncements. It is, of course, correct that 'All true judgments are mutually coherent'; but for that reason we cannot simply turn the statement around and say that 'All mutually coherent judgments are true.' Even the tyro in the science of correct thinking knows that a simple conversion of this sort is bad logic; the only permissible conversion must state that '*Some* mutually coherent judgments are true.' But this means that consistency or coherence as such is not necessarily a guarantee of all truth. Idealism, for instance, as a system of thought may have coherence *in itself*, but we have already shown that idealism is based on the initial fallacy of the 'idealist postulate' that we cannot transcend our mental states; of what value, then, is its internal coherence as a 'system'? The Ptolemaic theory of a geocentric planet-system was also coherent, but astronomy has definitely established that it is false and that the Copernican theory of a heliocentric system is correct. Consequently, the mere coherence of a particular judgment with a general system of knowledge is not in itself sufficient to establish its

particular truth. Since idealism as a system is false, the criterion of coherence, based on it, is also false.

Furthermore, ordinary *existential judgments* cannot be distinguished as true or false by their coherence with a general system of co-ordinated judgments. Consider judgments like the following: 'It is snowing today'; 'I feel chilly'; 'this paper is white'; 'my pen is out of order.' In what possible way could such mental pronouncements be judged to be true or false by examining their coherence with the systematic body of truths contained in physics, chemistry, biology, astro-physics, or philosophy? Yet they must be true or false. The criterion of coherence, however, will never enable me to decide whether they are true or not. Now, the greatest number of our judgments concern everyday matters like the above; they are inconsequential in themselves, but we must be able to decide whether they agree with reality and as such are true or false. The criterion of coherence is thus seen to be useless.

If driven to its logical conclusion, the theory of coherence will demand that we must have an almost *omniscient knowledge*, otherwise a particular judgment might be in coherence with one system and not in coherence with another. Or shall we say that it must only be consistent with *our own system*? Then the criterion is purely *subjectivistic* and *relativistic*, but that is precisely what a criterion of truth is not supposed to be, because its function should be to tell us whether our judgment is in accordance with the *reality* we are interpreting and not merely with our preconceived and subjective idea of it.

Coherence, therefore, is inadequate as the criterion of truth.

FIDEISM AND TRADITIONALISM

Some thinkers, anxious to stem the tide of mental anarchy resulting from the philosophy of Descartes, discredited the power of human reason to reach truth without the aid of some external criterion. They defended the theory that faith or tradition must furnish the ultimate guarantee of the truth of our knowledge.

Pascal (1623—1662), though not a skeptic, maintained that reason was too impotent to arrive at any certitude regarding the great truths which shape the destiny of man, like the existence of God, the immortality of the soul, revelation, and Christianity; we must begin our knowledge with an act of *faith*. *Huet* (1630—1721) demanded the acceptance of Divine Revelation as a basis of certitude; reason can give nothing more than probability in knowledge. That is traditional or historical *fideism*.

This view is extreme. Concerning *supernatural* truths it is indeed correct to say that a revelation is required in order to be certain of them; but it is absurd to think that a divine manifestation is necessary for *natural* truths of the ordinary kind. Why should we need revelation to obtain certitude that 'Wood floats,' 'water freezes,' 'light travels with a speed of over 186,000 miles a second,' 'fire burns,' and a thousand similar facts of the material and natural order? Besides, if we are to believe in a Divine Revelation, we must have *prior certitude* that God really exists and that

He has actually revealed certain truths; otherwise our act of faith would be blind and lack a rational foundation. The existence of God, however, cannot be clear to our intellect except through a process of reasoning based on the objective evidence of the Principle of Causality as applied to the world around us. Consequently, objective evidence, not faith, is the ultimate criterion of truth in the order of natural knowledge.

Traditionalism owes its origin to *De Bonald* (1754—1840). According to his view God gave a primitive Revelation to mankind which is handed down as a *tradition* from generation to generation. This belief of mankind reveals itself particularly in *language*, which is not the product of man's rational thinking, but a direct gift from God. Without tradition man can know nothing; all knowledge is derived from it. The ultimate criterion is, therefore, the revelation and authority of God. *De Lamennais* (1782—1854) sought the criterion of truth in the *general agreement of mankind (le consentement universel)*, because that is the voice of God transmitting the primitive Revelation to the individual mind. *Bautain* (1795—1867), *Bannetty* (1798—1879), *Ventura* (1792—1861), and *Ubaghs* (1800—1875), held similar views. All agree in this that the fundamental act of knowledge consists in belief.

Such a belief, however, cannot be the ultimate criterion of truth. The argument against fideism applies here also: we must first have *evidence* that God exists, that He has revealed truths, that these truths have reached us unchanged, and that the instrument of its transmission is tradition or the universal agreement of mankind. Authority,

whether it be that of faith in revelation, tradition, or the general verdict of mankind, is an *external* criterion, and its validity must first be proved by *independent reasons* before it can be accepted as trustworthy and true. But this means that 'objective evidence' is the real criterion of truth.

THE TEST OF INCONCEIVABILITY

Spencer, Mill, and their followers, maintained that evolution produced in man's mind certain fixed modes of thought in virtue of which the mind makes necessary judgments, such as ' $2 + 2 = 4$,' 'the whole is greater than any of its parts,' 'every effect must have a cause,' 'a circle is round,' and so forth. In consequence of this fixed grooving of the mind in a definite direction, such judgments are considered to be necessarily true *because their opposites are inconceivable*. ' $2 + 2$ ' must be judged to be ' 4 ,' not because the terms of this judgment are self-evident in themselves, but because we cannot conceive that ' $2 + 2$ ' would be ' 3 ' or ' 5 ' or any other number. If evolution had developed our minds in a different way, ' $2 + 2$ ' might be ' 3 ' or ' 5 ' or any other number; but it so happened that now the inconceivability of ' $2 + 2 = 3$ ' or ' $2 + 2 = 5$ ' makes the judgment ' $2 + 2 = 4$ ' to be true. And the same applies to every 'true' judgment: it is true because its opposite is 'inconceivable.'

This inconceivability of the opposite is, then, the ultimate criterion of truth.

This theory hardly needs refutation after what has been said before. Evolution, as we have seen, cannot give an adequate explanation of the *absolute* necessity of our

axiomatic judgments. We have shown that it is the intellectual *insight* into the self-evident relation existing between the ideas of such judgments in themselves which compels our assent to them as necessarily true. Consequently, it is not through their *opposites* that we perceive them to be true. Take the judgment, 'A circle is round.' If and when I know that 'A circle is a plane figure, comprehended by a single curved line, each part of which is equidistant from a common center,' then I know also that it *must* be 'round,' because that is what is meant by the concept 'round.' I do not need to compare the figure of a circle with a triangle, or a square, or a parallelogram, or a hexagon, or a parallelopipedon; all that is required is that I understand the terms contained in the judgment 'A circle is round,' in order to see that it is true. Were Spencer's criterion correct, I would first have to compare the figure of a circle with *every other* geometrical figure and see that it is 'inconceivable' that the circle be this or that or the other figure, before I could know that the circle *itself* is round. The reverse is true: I perceive clearly that the judgment 'A circle is square' is inconceivable, because I see it to be self-evident that 'A circle *must* be round'; it is only *after* I know that 'roundness' is contained in the idea of 'circle' that I realize that any other figure, like a square, triangle, etc., is not contained in the idea of 'circle.' In other words, the Principle of Contradiction is based on the Principle of Identity, and not vice versa. Hence, the self-evidence of the judgments themselves, and not the inconceivability of their contradictories, is the ultimate criterion of truth.

EPISTEMOLOGICAL MONISM

Neo-realism, in its effort to escape from idealism, went to the opposite extreme: it advocated an epistemological monism which is pan-objectivistic, because it ends by *identifying* the knowing *mind* with the known *object*. "When things are known, they *are* ideas of the mind. . . . Ideas are only things in a certain relation; or, things, in respect of being known, are ideas.... The difference between knowledge and things, like that between mind and body, is a relational and functional difference, and not a difference of content. . . . We have become wedded or indeed welded to the phrase — my thought is of an object — when we ought to say and mean — my thought is a portion of the object — or better still — a portion of the object is my thought: — exactly as a portion of the sky is the zenith."¹ Consciousness itself is merely a 'class of things'; consciousness is not of things, but things themselves are conscious by the mere fact that they are responded to by another entity. In this manner, according to the neo-realists, consciousness is numerically identical with the object of which we are conscious, the Ego with the non-Ego, the mind with nature, the ideas with the things thought of.

This makes the problem of knowledge extremely simple, because it eliminates the mind entirely from the process of knowledge; the only existent realities are the things themselves. Knowledge must always correspond to reality in this theory, because they are both identical. But therein neo-realism *refutes itself*. If we are certain of anything through our consciousness, it is of the fact that we are *not*

identical with the objects of which we are conscious. When I am aware of the photograph or paper on my desk, it is futile for me to think that it is not I who am conscious of the photograph and paper, but that it is the *photograph* itself and the *paper* itself which is conscious. We have proved elsewhere that mind and matter, Ego and non-Ego, the mental and extra-mental, are distinct realities which are not identical in being; to eliminate the mind will never solve the problem of knowledge.

If our consciousness is identical with the objects of which we are conscious, then, of course, our judgments should *always* correspond to reality and be true. But that is not the whole of the problem of knowledge; we must also explain the possibility and fact of *error*. When, however, we assert that the knowledge of objects and the objects of knowledge are identical in being, there is simply *no possibility of error* in judgments; and that is contrary to *fact and experience*. Neo-realists are not always consistent in their teachings. They frequently speak of the mind and the world as really distinct in being. When, however, they explain the nature of the mind and identify it with the objects known (as they do), they deprive both truth and error of all meaning; because under such circumstances any conformity or disconformity between mind and *reality* is out of the question. A theory that can give no intelligible explanation of truth and error is false and untenable.

THE CRITERION OF COMMON SENSE

The criteria investigated above are of the intellectual type. Others are non-intellectual in character, in as much as they are not founded on the intellectual nature of man.

The Scottish School places the criterion of truth in the common sense of man. *Thomas Reid* (1710—1796), the real founder of this school of thought, insisted that our knowledge is based on principles which are evident and are recognized as such by the 'common sense' of man; from these principles man derives a body of primordial 'truths of common sense' which serve as a sort of general fund of knowledge for mankind. So far no objection can be raised against him and his followers, because this view conforms to the doctrine of 'objective evidence' as the criterion of truth. At times, however, the Scottish philosophers seem to teach very plainly that these fundamental principles are accepted through an *instinctive impulse* of human nature, rather than through an *intellectual insight* into the objective truth. In that case, then, the ultimate criterion would consist in some sort of *belief* in the rationality of this impulse, and not in the self-evidence of reality manifesting itself to the mind. Other adherents of the 'common sense' doctrine are *James Oswald* (1727—1793), *James Beattie* (1735—1803), *Dugald Stewart* (1753—1828), and *Thomas Brown* (1778—1820).

If 'common sense' be interpreted as a kind of instinctive belief, it is obviously only a *subjective* criterion of truth and motive of certitude, and as such it is inadequate. Belief necessarily presupposes an *insight* into the *grounds* of this belief, before it can be used as an intelligent guide. We must be sure *beforehand* on indisputable evidence that such an

instinct exists in our nature, that it is reliable and not prone to error, and that it can give us intellectual certitude. If these conditions are not present and known to be present, we can have no assurance that our knowledge is true; we would indeed feel the subjective necessity to judge as we do, but we could never verify our judgments and see whether they agree with reality. Now, either we know the grounds of this belief, or we are ignorant of them. If we are *ignorant* of them, our instinctive belief is blind and without rational foundation; and then it is useless as a criterion of truth, because it is contrary to the nature of the mind as an essentially 'cognitive' faculty to be determined in its knowledge by a blind instinct. And if we know the grounds of this belief, then the 'objective evidence' of these grounds, and not the belief itself, is the ultimate criterion.

CRITICAL REALISM

Critical realists make a clear distinction between the knowing mind and the objects known: mind and world are diverse realities. The world is known by the mind by means of certain 'characters' or 'essences.' These latter imply "a reference to, and an acceptance of, a real, extra-experiential universe of existents. It is not that we reason to, or infer, such a fact beyond experience. The *belief* is rather an *assumption* which we make by *instinct*, since it is only by *taking for granted* that we are in relation to realities on which the needs of life depend that we are able to maintain ourselves alive at all. . . . An 'object,' therefore, is constituted by a group of characters with which

psychological experience makes us familiar, *plus the instinctive sense* that there is something present of which we have to take account, the latter aspect being the outcome of that state of muscular tension which is conditioned by our nature as active beings dependent on an enviroing world, while the characters are used, also *instinctively*, to give this a specific form.”² We intuit the ‘characters’ or essences directly, and these we refer to a physically existing object by means of an *instinctive impulse* of our nature. The ultimate criterion of truth is, therefore, not the ‘objective evidence’ of reality as such, but a belief and an assumption, made by instinct, that these ‘characters’ or ‘essences’ reveal reality as it is.

J.E. Turner very pointedly sums up the situation for critical realism as follows: “All realisms . . . must finally rest, exactly as naive realism does, upon the process and content of perception — upon this content as more keenly criticized and more rigidly tested; and this analysis must be pursued to a final verdict. If then this content is regarded as not in itself physical, two alternatives arise: either physical reality is never ontologically identical with perceived content, and therefore, since there is no other mode of directly apprehending it, this reality is noumenal; or realism must fall back on an instinctive, but non-philosophic, belief in the known existence of physical reality. This dilemma faces critical realism. If it maintains its universal distinction between physical things themselves beyond our consciousness, and their perceived or apparent sense-characters, then it becomes a noumenalism. But if, on the other hand, it founds its affirmations on instinctive belief, it

forfeits all title to be regarded as a philosophic system, whatever other merits it may possess. Or at best it can become a philosophy only of the content of perception as distinct from physical reality itself."³ In neither alternative can we have a *rational* foundation for our certitude that our judgments correspond to reality; our ultimate criterion of truth would be either *blind instinct* or an unproved and unprovable *assumption*. But such a criterion is *subjectivistic* and useless.

PRAGMATISM AND HUMANISM

Pragmatism, or *Humanism*, is a system of thought which is voluntaristic. The truth of judgments does not arise from their correspondence to reality. The pragmatist criterion of truth consists in the *utility* of a belief in satisfying *human needs* in a social way. That is true which 'works,' which has practical value, which leads to beneficial results for human progress, which promotes the best interest of mankind through living experience. Results *make* a belief true or false for the time being. Beliefs *become* true, when they function for the social welfare of humanity; and false, when they cease to function along these lines. Truth is, therefore, nothing static and immutable, but something dynamic and perpetually changing. Consequently, a belief may be true at one stage of development, and the same belief may be false at a different stage; something may be true under one set of conditions and false under another; a theory may be true for one class of people and false for another class, depending on the intellectual and cultural conditions

prevailing at a particular time and in a particular locality. Truth, as will be seen, is entirely *subjective* in character.

This interpretation of truth is contrary to the accepted *meaning* attached to the word by all men, whether educated or uneducated, and amounts to a *perversion of language*. To identify 'truth' with 'utility' is nothing less than to reduce the 'true' to the 'good.' The 'good,' however, is the object of the *will*, not of the intellect, while the 'true' has been considered by men at all times to be the proper object of the *intellect*. A lamentable confusion of thought must result from this identification of the 'true' with the 'good.' If both are identical, so that 'truth' is the object of the will, what can possibly be the *object of the intellect*? As a natural faculty of man it must have a natural object, just as well as the will; but if we remove 'truth' from the intellect, the latter is without a proper object with which to exercise its power. The exercise of any power or faculty involves the striving to *realize something*, and that demands an object within its own proper sphere of activity. Every power or faculty of the human organism, internal as well as external, has its proper object; the will, for instance, strives toward the realization of the 'good.' But what could possibly be the object of the intellect except the realization and acquisition of 'truth'? There is no other object assignable or discoverable. Pragmatists may *assert* that the 'true' is identical with the 'good,' but that will never *really* identify such totally disparate things. Their attitude is unjustifiable, because contrary to the fundamental conceptions of men.

Besides, in identifying the 'true' with the 'good, pragmatists *do not solve the epistemological problem of knowledge*. The problem of 'knowledge' remains just as acute as before: it cannot be solved by transferring the concept of 'truth' from the field of knowledge to the field of action and then denying that a 'problem of knowledge' exists. We must still answer the questions: Is there an objective reality which is extra-mental? Can this reality be known? How is it known? How do our judgments interpret this reality? Do they correspond with it? How can we have certitude about this? These questions constitute the 'problem of knowledge' and the mind of man will not be satisfied, and will continue to exert its powers of reasoning, until these questions are answered or until the mind sinks in despair into skepticism. But ignore this problem the mind cannot. Whether we call the answers to these questions 'truth' or whether we give it another name, makes little difference: it is the problem and its solution that count, and they pertain to the province of the *intellect* and must be solved by the intellect and not by the will. Pragmatism, therefore, does not solve the problem of knowledge by dubbing it 'metaphysics' and then ignoring its existence.

And pragmatists are *inconsistent*. They identify 'truth' with 'utility' and thus transfer it to the province of the will. Nevertheless, they appeal to the *intellect* with a great array of arguments, to prove that 'truth' is to be judged according to its beneficial results. Thereby they surreptitiously substitute the intellect for the will as the arbiter of truth and error and unconsciously admit after all that it is the *intellect*, and not the will, which must decide whether their

theory or opposite theories give the correct (or 'true') solution of the problem of knowledge and truth. Since they appeal to the reasoning intellect, they must abide by its verdict. Now, it is the verdict of the reasoning intellect, as we have shown, that truth is found in the *judgment interpreting reality* and not in the results which flow from a certain belief. It is not 'utility' which determines the 'truth' of judgments, beliefs, and theories, but the objective evidence of reality. In fact, when pragmatists attempt to prove their own theory, they marshal numerous facts and reasons in order to show that 'utility' and not 'objective evidence' is the criterion of truth and the motive of certitude; and in doing so, they appeal to the *objective evidence* of these facts and reasons to establish their case. Their own attitude and action is their best refutation.

Moreover, pragmatists claim that those beliefs are 'true' which satisfy human needs and produce beneficial results for man in a social way. What needs, and what *beneficial results*? We must know them, so as to be able to ascertain which beliefs contain 'truth' and which 'error.' In order to know whether needs are real or apparent and whether results are beneficial or harmful, it is necessary for the intellect to discover the *facts* regarding these needs and results and then pass *judgment* on the truth or error of the beliefs. But here again, if any judgment corresponds to the facts at issue, it is 'true'; and if it does not, it is 'false.' Thus it can be seen that truth and error reside in the judgment and their presence is determined by the objective evidence of the facts. The good results may be taken as an index or *sign* of truth, but the ultimate *criterion* of truth lies in the

objective evidence before the mind. As long as it is necessary to have a criterion to discriminate between 'real' and 'apparent' needs, between 'beneficial' and 'harmful' results, between beliefs which 'work' and those which 'do not work,' results cannot be considered the ultimate criterion. Results do not appear with labels attached; they can be discerned only by the intellect. Even from a pragmatist standpoint, then, the truth or error of beliefs cannot be decided without the judging power of the intellect. The ultimate criterion for the intellect, however, as has been seen, consists in the clear self-manifestation of reality or *self-evidence*. Hence, pragmatism does not satisfy the 'needs' of the intellect as a theory of truth and knowledge and, judged by its own criterion, is unsatisfactory and therefore false.

Finally, how can I apply the pragmatist criterion to everyday *existential judgments*? I judge that 'My watch is slow,' 'a car is passing,' 'my feet are cold,' and so on. These statements contain truth or error. By what possible results for human progress and welfare am I to decide whether they are true or false? Or will a pragmatist seriously assert that there is no truth or error in these and similar judgments? If he claims there is not, we must dissent; if he agrees that there is, he must admit that his criterion does not apply. A criterion, however, which fails in its essential function, is *worthless*, because it is no criterion at all: it does not 'work.'

RELATIVISM AND TRUTH

There is *relativity in all knowledge*. By the very fact that a thing becomes known, a relation is established between it and the knowing subject. In order that an object be 'known,' it must be cognitively present *to* the knower and be consciously apprehended by the knower; thereby both object and subject obtain a 'reference to,' or 'relation toward,' each other. To say that the mind could know an object without any relation existing between them, would be the same as to say that an object could be known without being 'known' and a subject could know without 'knowing'; but that would be absurd. When we say that the mind can know reality 'as it is in itself independent of the mind,' we do not mean to claim that reality, when known, is independent of the mind in the act of *knowledge*, but that it is independent of the mind in its extra-mental *existence*.

Maher has given a true and succinct expression of the relativity of knowledge, when he states — "(A) that we can only know as much as our faculties, limited in number and range, can reveal to us; (B) that these faculties can inform us of objects only so far, and according as the latter manifest themselves; (C) that accordingly (a) there may remain always an indefinite number of qualities which we do not know, and (b) what is known must be set in relation to the mind, and can only be known in such relation."⁴ This, however, is not the usual meaning attached to the phrase in modern philosophy. *Relativity of knowledge* there means that character of knowledge in virtue of which it has only *relative value*, i.e., knowledge is not immutably and absolutely true in itself, but is true only according to the mental laws and conditions of the knowing subject. The

theory which teaches this doctrine, is called *relativism*. Since knowledge is true only for the individual subject who possesses it and is determined by his peculiar mental constitution, it is also subjective in character. Relativism is thus equivalent to *subjectivism*.

According to relativism, then, knowledge and truth have no absolute and permanent validity: they are valid only for man as he is at present constituted, because they are the immediate product of his cognitional processes, and these processes operate according to the laws which govern his particular organism. Our knowledge of the extra-mental universe, for instance, is valid for man, but that does not mean that this knowledge corresponds to *reality as it is*. All forms of idealism and representative realism are thus seen to be relativistic, in as much as these theories subscribe to the doctrine that we can know nothing but our internal *subjective* states of the mind. Mentalists deny the existence of extra-mental reality altogether; representational realists, like Kant, Spencer, Mill, Huxley, and the adherents of sensism, positivism, and pragmatism, admit the existence of extra-mental reality, but they maintain that the knowledge of this reality is so transformed and transfigured in perception and intellection as to give no insight into what reality *actually is*. Such is the nature of all human knowledge and truth — it is relative and subjective, without objective validity. *Protagoras* (born about 480 B.C.) already defended this doctrine, asserting that “man is the measure of all things.”

Relativism attacks the very nature of knowledge and truth in their foundation. It would be next to impossible to

convince a confirmed relativist of the erroneousness of his position, because, like the universal skeptic, he admits no fixed and objectively valid laws of reasoning. But for those who still have an open mind it must be clear that *relativism is false*. If there are no truths which are absolutely valid, then even the Principles of Identity, Contradiction, Excluded Middle, and Sufficient Reason possess only relative, temporary, ephemeral value. They are true *now* for *us*, due to the subjective constitution of our mind; but they need not be true in *themselves*, nor need they have been true always in the past, nor need they be always true in the *future*. But the consequences of such a doctrine are absurd in the extreme. There could then have been a time, or a time may come, when it would be possible 'to exist' and 'not to exist' at the same moment; to be an 'entity' and also a 'non-entity' at the same moment; in fact, it would be possible to be *neither* an 'entity' *nor* a 'non-entity,' but something between 'entity' and 'non-entity,' at the same moment. And it would also be possible for knowledge to be 'true' and 'false' simultaneously. These are the inevitable consequences of relativism, if consistently carried to its logical conclusions.

That relativism actually leads to the renunciation of the Principle of Contradiction, at least by implication, can be seen in the most recent of epistemological theories, that of *objective relativism*. According to this theory, knowledge is relative, but this relativity is objective in the datum or character-quality of the thing as perceived. What I am aware of in perceiving a thing is its *quality* or its set of qualities; it is this that I perceive, and not the thing itself. "The qualities are not the existent, to be sure, but they are

its whole nature, and it has no other.”⁵ When perceiving an orange, I perceive the qualities ‘yellowness’ and ‘roundness’; these qualities “are its whole nature, and it has no other”; as such, then, these qualities constitute the objective essence of the orange. The result of this doctrine is that these qualities will be *objectively* that what they *appear* to be, *relative* to each individual from his particular *point of view*. The classic example is that of the penny. You and I look at it from different points of view. From where I stand, it appears as ‘circular’; from where you stand, it appears as ‘elliptical.’ Since our knowledge of these qualities is relatively true to each of us, and since these qualities are objectively the only thing we know of the penny, it follows (according to the theory of objective relativism) that the penny is really and *objectively circular and elliptical at the same time*, since we both look at it at the same time.

The implication of such a relativistic theory is obvious. Things can really have a different size, shape, color, temperature, etc., at one and the same moment; because as things *appear*, they *are*, i.e., to us. As Edward F. Talbot justly observes: “A knowledge of reality becomes an impossibility, since we know things not as they are, but as they appear. Appearances become all; reality vanishes. In becoming all, appearance becomes nothing. There is no common appearance, no unity of perception. Each appearance is proper to a particular point of view and the content present to the different subjects varies not only numerically but qualitatively. Thus we know not reality, and

appearance finally fades into the projection of a point of view.”⁶

Objective relativism, and every other theory of relativism, thus involves a denial of the most fundamental laws of being and thought — the Principles of Identity, Contradiction, and Excluded Middle. But to destroy their validity means to destroy the very possibility of valid knowledge. The truth of relativism and the truth of the First Principles are *incompatible*. If the First Principles are allowed to stand in their objective validity, relativism is false; but if relativism is accepted, the First Principles must fall as invalid illusions, and all knowledge, *including relativism* as a theory of knowledge, must fall with them. But that would be the suicide of reason and the triumph of universal skepticism. Relativism, therefore, must be rejected, and truth must be taken as something absolute in an objective sense.

So far as the criterion of objective relativism is concerned, it must consist in the *appearance* of the ‘character or essence. This being the only thing we can know about an object, it is plain that our judgments must *always* correspond to it. As such, then, our judgments will always be relatively and subjectively true. But here again the criterion fails as a criterion because it will never enable the mind to discriminate between ‘true’ and ‘false’ appearances. In fact, there can be no such thing as *error* in this system, because every appearance is ‘true’ for each individual according to his subjective point of view. This, however, contradicts experience; error is a fact, and it must be accounted for. Since the objective difference between

truth and error is obliterated in relativism, it is a false system of knowledge.

By exposing the inadequacies and absurdities contained in these various theories regarding the nature of truth and the criterion of truth, we have confirmed the doctrine that the

ultimate criterion of truth and motive of certitude consist in the internal, immediate objective evidence of reality manifesting itself to the intellect. And thereby another spontaneous conviction of man has been critically examined and philosophically vindicated, namely, that the *judgments* of the intellect are a true and valid source of knowledge in interpreting reality.

SUMMARY OF CHAPTER XVII

Various philosophers have advanced different criteria of truth, depending on their general theory of knowledge.

1. *Descartes* considered 'clear and distinct ideas' to be the criterion. This would not guarantee the correspondence of the idea with reality. *Malebranche* contended that we know all things through an intuition of them in the Mind of God; *Rosmini* claimed that we know all things through an intuition of Being. This is contrary to our experience.

2. *Idealistic monism* finds the criterion in *coherence* or consistency. But even a false system may be coherent. By this criterion we could not distinguish between true and false 'existential judgments.' To know whether a particular judgment is coherent with a system of knowledge would practically demand omniscience.

3. *Fideism and Traditionalism*. Fideism takes 'faith' and traditionalism takes 'tradition' as the criterion. But before we can accept such an external criterion, we must *have prior certitude* about the validity of the authority demanding this act of faith.

4. *Inconceivability of the Opposite*. Judgments are supposed to be true, because their contradictories are 'inconceivable.' If this were true, a statement would have to be compared with its opposite, before its truth could be ascertained. But First Principles are seen to be absolutely true through a direct comparison of the *concepts* of the judgment, not by a comparison of these principles with their contradictories.

5. *Epistemological Monism (Neo-Realism)*. In this theory the mind is reduced to the object known. This is contrary to all experience. If there is no real mind, distinct from the object known, *error is impossible*; but error is a fact.

6. *Common Sense*. The Scottish School places the criterion in the dictates of 'common sense' which it conceives as based on a *blind* instinct. Belief, then, is the foundation of knowledge. If we are ignorant of the grounds of this belief, it is blind and irrational; if we know these grounds, then objective evidence is the criterion, and not belief.

7. *Critical Realism*. We perceive the 'characters or essences' of things and refer them to reality through an *instinctive belief* that these 'characters' are real qualities of things. This means that our knowledge is *not rational*. We could never know whether these 'characters' correspond to reality; we could, then, never distinguish between true and false knowledge.

8. *Pragmatism and Humanism*. 'Utility' is the criterion of truth: beliefs are 'true,' if they produce 'beneficial results.' This is a confusion of the 'true' with the 'good'; and since the 'good' is the object of the will, the intellect would be without an object. This theory evades, but does not solve, the problem of knowledge. Pragmatists are inconsistent, because they appeal to the *intellect* to prove that their theory is 'true.' In order to apply the criterion, we would have to discriminate between 'real' and 'apparent' needs, 'beneficial' and 'harmful' results; but only the intellect can do that through an insight into the *facts* — and then objective evidence is the criterion. Ordinary 'existential

judgments' cannot be judged as 'true' or 'false' according to beneficial results for humanity.

9. *Relativism*. Truth and knowledge have only relative value, according to the laws and conditions of the individual mind; truth is nothing permanent, absolute, and necessary. In that case the First Principles of Identity, Contradiction, and Excluded Middle have only relative validity. *Objective relativism* implies the denial of these principles. But that means the destruction of all knowledge and truth and leads to *skepticism*.

Chapter 18

THE TRUTH-VALUE OF REASONING

PERCEPTS LEAD TO CONCEPTS, CONCEPTS TO JUDGMENTS, AND judgments contain truth or error in their interpretative pronouncement about reality. The result of our examination into their validity has vindicated man's spontaneous conviction that human knowledge is essentially trustworthy. Much of our true knowledge is acquired directly by means of immediate sense-perception and by an analysis of fundamental abstract concepts. But reality is often so complex and recondite that it is not self-evident to the mind contemplating it. Many truths cannot be discovered by means of immediate sense-perception as such or by means of a simple comparison of the concepts contained in a judgment. A mediate process of intellection is required in order to disclose the hidden truth. This is the process of *reasoning* or *ratiocination*.

Reasoning is that mental process in which, from truths already known, we *infer* some other truth contained in them and following from them with necessary consequence. The inference draws out and makes explicit a truth which is implicitly present in other truths. This can be done in two ways. We can argue from the logical whole to a logical part

of the whole, and then we have a process of *deduction*; or, we can reason from the truth of the logical parts to the truth of the logical whole, and that is the process of *induction*. In the former the inference goes from the more universal to the less universal or particular, and in the latter from the particulars or less universal to the more universal.

Serious objections have been raised against the inferential process involved in deduction and induction. Some philosophers claim that there is an essential flaw in the very nature of these processes. If deduction and induction, they say, are as described, they are incapable of leading the mind to a certain knowledge of new truths and are, therefore, useless as *inferences*. This attack on the validity of deduction and induction is really an attack on the validity of human reason as a source of knowledge and cannot pass unchallenged.

THE PROBLEM OF DEDUCTION

Francis Bacon (1561—1626) criticized the syllogistic or deductive method as being of no value for the acquisition of real knowledge; instead, he advocated the careful study of nature by means of inductive analysis. Whatever value the syllogism may have is due to the fact that it is based on induction. The *empiricists* and *positivists*, since their theory of knowledge is sensistic, also reject the inferential validity of deductive reasoning as exemplified in the syllogism, because this form of argumentation reasons from the truth of the universals to the truth of the particulars, and sensism will not admit that we have genuinely universal

ideas. *John Stuart Mill* launched a vigorous attack on the syllogism as a form of inference. He has this to say:

“It must be granted that in every syllogism, considered as an argument to prove the conclusion, there is a *petitia principii* [a begging of the question]. When we say,

All men are mortal,
Socrates is a man,
Therefore Socrates is mortal,

it is unanswerably urged by the adversaries of the syllogistic theory, that the proposition, Socrates is mortal, is presupposed in the more general assumption, All men are mortal: that we cannot be assured of the mortality of all men, unless we are already certain of the mortality of every individual man: that if it is still doubtful whether Socrates, or any other individual we choose to name, be mortal or not, the same degree of uncertainty must hang over the assertion, All men are mortal: that the general principle, instead of being given as evidence of the particular case cannot itself be taken for true without exception, until every shadow of doubt which could affect any case comprised with it, is dispelled by evidence *aliunde* [from an outside source]; and then what remains for the syllogism to prove? That, in short, no reasoning from generals to particulars can, as such, prove anything, since from a general principle we cannot infer any particulars but those which the principle itself assumes as known.”¹

Mill’s line of argument is plain: the conclusion is *already contained and known* in the major premise; for the major

premise ('All men are mortal') could not be known to be true, if it were not also previously known that the conclusion is true ('Socrates is mortal'). We must be certain that this conclusion is true before we can assume the truth of the major premise, because the truth of the major premise could not be clear without the truth of the conclusion. And yet, by the very fact that we are attempting to prove the conclusion we admit that we are *not certain* that the conclusion ('Socrates is mortal') is true; and that necessarily implies that we are *not certain* of the truth of the major premise. But to prove something from an uncertain and doubtful premise, is an illogical process. On the other hand, if we maintain that the major premise ('All men are mortal') is really certain, then it follows that we must also have known before making the syllogism that the conclusion ('Socrates is mortal') is true and certain; but in that case, why make the futile attempt of proving something which is already known and certain? In the first instance we have a flagrant begging of the question, and in the second instance we are not acquiring a new truth. In both instances the syllogism is useless as an inference, because we have either an *illogical inference or no real inference* at all. Such is the nature of Mill's argument.

Mill himself explains how we, according to his view, arrive at the general proposition ('All men are mortal') used as the major premise. Changing from 'Socrates' to 'the Duke of Wellington,' he states: "Assuming that the proposition, The Duke of Wellington is mortal, is immediately an inference from the proposition, All men are mortal; whence do we derive our knowledge of that general

truth? Of course from observation. Now, all which man can observe are individual cases. From these all general truths must be drawn, and into these they may be again resolved; *for a general truth is but an aggregate of particular truths*; a comprehensive expression, by which an indefinite number of individual facts are affirmed or denied at once. But a general proposition is not merely a compendious form for recording and preserving in the memory of a number of particular facts, all of which have been observed. Generalization is not a process of mere naming, it is also a process of inference. From instances which we have observed, we feel warranted in concluding, that what we found true in those instances, holds in all similar ones, past, present, and future, however numerous they may be. We then, by that valuable contrivance of language which enables us to speak of many as if they were one, record all that we have observed, together with all that we infer from our observation, in one concise expression."²

In this interesting passage Mill's sensism and nominalism is apparent. The major premise expresses a general truth; and this "general truth is but an *aggregate* of particular truths." The meaning of Mill is clear: we have *collective* propositions, but none that are truly universal. They give us a "comprehensive expression, by which an indefinite number of individual facts are affirmed or denied at once"; again, this must be understood in the sense of a 'collective,' not a 'universal,' proposition. Mill then shows how the truth of the major premise is the result of an *inductive* process; and he continues: "When, therefore, we conclude from the death of John and Thomas, and every

other person we ever heard of in whose case the experiment had been fairly tried, that the Duke of Wellington is mortal like the rest, we may, indeed, pass through the generalization, All men are mortal, as an intermediate stage; but it is not in the latter half of the process, the descent from all men to the Duke of Wellington, that the inference resides. The inference is finished when we have asserted that all men are mortal.”³

Mill did not realize it, but in giving this explanation of the genesis of the major premise he ruined the whole value of his initial argument against the validity of the syllogism as a legitimate inference. He himself furnishes the clue which establishes the truth-value of deduction.

THE TRUTH-VALUE OF DEDUCTION

Mill is perfectly correct when he states that we arrive at the truth of the major premise (‘All men are mortal’) by means of an inductive process of reasoning. But how is this induction made? By a complete enumeration of *all* instances? Not at all. It is impossible for us to observe all the instances which are included in a general statement; we can observe no more than a very limited number. Now — and this is vital — “from instances which we have observed, we feel warranted in concluding, that what we found true in those instances, holds in all similar ones, past, present, and future, however numerous they may be.” It is interesting that Mill, the empiricist, includes even the ‘future’ cases in this generalization. The main point is that Mill admits that we can make a legitimate inference from a *limited* number

to a generalization which embraces 'all similar ones' in the 'past, present, and future'; and that necessarily means that the inference applies also to those not *previously known* and not known *at the time* the generalization is made. But this is a fatal admission.

In his initial attack on the validity of the syllogism, Mill contended that we could not know that 'All men are mortal,' unless we had a *previous* knowledge that 'Socrates is mortal.' This contention really asserts that we could not know 'All men are mortal' except through the fact of a *complete* enumeration which, naturally, would then also include 'Socrates' as one of those whom we had perceived to be mortal. Now, Mill admits that 'Socrates' might not have been one of those whose death, like that of 'John' and 'Thomas,' we had actually observed; he could be one of 'the similar ones, past, present, or future,' of whom we have had *no previous* knowledge as to their mortality. Since I felt 'warranted in concluding' that 'All men are mortal,' notwithstanding the fact that I had no previous knowledge of the mortality of 'Socrates,' I can most assuredly *now conclude* that 'Socrates is mortal.' In making this deduction, Mill can no longer assert that the truth of the major premise ('All men are mortal') *depends* on the truth of the conclusion ('Socrates is mortal'), because the truth of this major premise was established *independently* of the truth of the conclusion; it was only from the mortality of 'John' and 'Thomas' and some others that I felt warranted in concluding that 'All men are mortal,' while 'Socrates' and his mortality never entered the inductive process at the time it was made. There will, then, be no begging of the

question, when I apply the general truth contained in the major premise to a particular instance, as long as the latter was not involved in the induction which gave me the general truth in the first place. Mill's argument is, therefore, fallacious.

As long as we are 'warranted in concluding' from an *incomplete enumeration* to a universal proposition, so that *not all* the particular instances are *previously* known, we can legitimately infer the truth of those not previously known by drawing them under the extension of the universal proposition. Such an instance, of course, will be contained in the major premise as a matter of fact, but this fact is not actually known to me until I make the deduction; in other words, the conclusion is *virtually* contained and known in the major premise, but not *formally*. And since only that which is 'formally known' is 'actually' known by me, I do really acquire a *new* knowledge when I deduce the truth of the conclusion from the truth of the universal proposition used as the major premise.

LET US TAKE A CONCRETE EXAMPLE. I READ IN CHEMISTRY THAT 'All substances consisting of carbon are combustible.' Scientists arrived at this generalization through the process of an extensive, though not complete, induction: wherever and whenever the experiment was made, carbon was found to be combustible. Does that also apply to diamonds? Certainly; but *I do not know* as yet that diamonds consist of carbon; I am under the impression that diamonds are a sort of quartz. A year later I read an article on diamonds and

discover that they consist of carbon. Do I now know that 'diamonds are combustible'? Not yet. While reading about diamonds, I do not think at all about the truth I learned a year before that 'All substances consisting of carbon are combustible.' Then one day it occurs to me *simultaneously* that 'All substances consisting of carbon are combustible' and that 'Diamonds consist of carbon.' And *now* it first dawns on my mind through deduction: 'Well, then, diamonds are *also* combustible,' and I have acquired a *new* knowledge about diamonds. Up to this point I had a knowledge of both facts, 'Carbon is combustible' and 'Diamonds are carbon,' taken separately and without realizing their implication. It was only when both truths are brought *together* before my mind and I realize the *logical connection* existing between them, that I am able to make the deductive syllogism and draw out the necessary conclusion:

All substances consisting of carbon are combustible;
Diamonds consist of carbon;
Ergo, diamonds are combustible.

We find many cases of this kind, where deduction is found to be a perfectly legitimate *inference*. Science, for example, includes in the class of 'mammals' all animals that breathe through lungs, have hair on the body, and suckle their young. Now, the *whale* lives in water and has the general shape of a fish. Upon closer examination, however the whale was found to breathe through lungs (not gills), to have hair (not scales) on its body, and to suckle its young.

What conclusion had to be deduced from these premises? This, that whale is not a fish, but a mammal; and so it happens that now the whale is classified as a mammal. Here the argument was made from the universal truth to the particular instance by means of deduction.

In a similar manner, *Pasteur* established by induction that 'Germs derive their origin from parental germs through generation.' At the time practically nothing about germs was known; the number of known existing types was very small. Notwithstanding this meager knowledge, the general principle was proved by induction to be true. Since then many new types of germs have been discovered; we cannot, therefore, say that they were known at the time this general principle was formulated. Through a process of syllogistic *deduction*, however, we can now *prove* that every new type discovered must have originated through parental generation; and that is a truth of great value for prophylactic medicine.

Einstein maintains that inertia is the same as gravity; consequently all the effects of inertia can also be obtained through gravity. From this he deduced that the rays of light would be bent from a straight course by passing through a gravitational field. Thus, the rays of the stars, passing close to the sun on their way to the earth, should be bent in the direction of the sun. This would follow from his general theory of relativity. Observations of solar eclipses have shown that the light of stars *does* curve toward the sun while passing near by, although the degree of curvature did not seem to agree with the mathematical calculations of

Einstein. The point here, however, is that *deduction* can lead to *new* knowledge and truths.

Through deduction *Mme. Irene Joliot-Curie* and her husband *M. Frederic Joliot* came to the conclusion that, since radioactive elements change to lighter elements through disintegration, it must be possible to reverse the process and create the heavier elements artificially by *re-integration*. Thereupon, in 1934, they bombarded common elements, like aluminum, magnesium, and boron, with alpha particles and succeeded in transforming them temporarily into heavier elements. Following their lead, *Ernest O. Lawrence*, of the University of California, shot a stream of positively charged particles from a four-million-volt cathode tube into common table salt, and after a ten-hour bombardment the salt emitted the gamma rays of radium for a period of fifteen hours.

Some of the greatest achievements in astronomy and astrophysics have been made by means of deduction. From a conclusion drawn from the theorems of Conic Sections, *Kepler* established the general principle that certain definite positions are characteristic of an ellipse. Then, by showing that the orbit of Mars presents these definite positions, he concluded that the orbit of Mars is an ellipse. From Kepler's laws of motion the genius of Newton deduced the universal gravitation of matter. His discovery was brought about by one of the most brilliant series of deductive processes ever performed by man.⁴ Mathematics has always played a predominant part in the calculations of astronomy, and mathematics is essentially a deductive

science. But who would seriously question the validity of the deductions of mathematics?

The characteristic feature of deductive reasoning is this: the conclusion is virtually contained in the premises, but not formally. The truth of the conclusion becomes formally known through the syllogistic process. As such, then, the formally known truth becomes a new truth and extends our knowledge of reality. Consequently, deduction is a *valid inference* and a source of new knowledge. And this is borne out by the many scientific discoveries made through deductive reasoning, a few of which have been noted above.

THE PROBLEM OF INDUCTION

Induction, as well as deduction, contains a serious problem concerning its validity as a legitimate inference. In order to appreciate its seriousness it will be necessary to understand clearly wherein induction consists. *Induction* can be defined as *the legitimate inference of universal laws from individual cases*, or, to put it in different words, the logical transition from that which is less universal to that which is more universal.

Induction will be either complete or incomplete. It is complete when it consists of a mere totalization of the individual instances expressed in the general statement. If I know, for example, that every single member of a certain Legion Post was an infantryman, I can express this fact in the totalizing general statement that 'All members of this Post were infantry men.' This is what might be called, in Mill's phrase, an 'aggregate of individual truths.' Such an

induction has no value for science, because the statement will not apply to anyone outside this limited aggregation; it does not lead to a universal law applicable to members not included in the original inductive process. Any induction will be incomplete, if it is based upon the investigation of a limited number of instances. If these instances are too limited or are non-typical, it will as a rule be insufficient as an inferential process; but if the instances are relatively numerous and typical, it will be a case of scientific induction.

An incomplete *scientific induction* is one which is based on a limited number of instances and from these infers the constant and *necessary relations* existing between things or between the properties of things. The result of this induction is expressed in a *universal* statement which represents a *law of nature*, and as such applies to all instances of the past, present, and future, whether known or unknown, whether actual or merely possible. That science makes inductions of this kind and claims that they are valid and legitimate inferential processes of reasoning, leading to new truths and knowledge, need hardly be mentioned.

This, however, involves a serious problem. We know from logic that we cannot legitimately conclude from the truth of the particular to the truth of the universal; what is true of *some* need not be true of *all*. Because some' men tell lies, we cannot conclude that 'all' men tell lies; because 'some' soldiers were killed in battle, we cannot conclude that 'all' soldiers were killed; because 'some' animals have wings, we cannot conclude that 'all' animals have wings. The

conclusion may not be wider than the premises. But that seems to be the very procedure followed in the process of induction. From some instances observed we argue to 'all' instances, even to those unobserved and unknown. From a *number* of particular cases we formulate a law which is supposed to apply validly to the *entire class* of these and similar cases. Is science, then, not guilty of an *illicit process*? Does this not vitiate the entire inductive inference, making it illogical and therefore valueless for acquiring true knowledge? But if induction is a valid method of reasoning, on what *grounds* is its validity based, so that it is logically justified? Wherein does the *necessity* of the inductive law consist, since it seems to be built upon so insecure a foundation?

Different solutions have been offered, depending to a great extent upon the theory of reality and the theory of knowledge proposed by the various schools of thought. *Empiricists*, who defend a sensistic philosophy and admit no knowledge beyond that of sense-experience, concede only an empirical or experiential validity to the laws formulated by means of induction. Such a law is a mere generalization from observed facts and has no strict value beyond the limits of observation. Within these limits they give us *certitude*, but beyond these limits only *probability*. We, of course, are subjectively convinced that these laws apply in all cases at all times under all circumstances; but this conviction of the 'necessity' of such laws is the result of 'association'; it is a *psychological*, not a logical, necessity. That is why Mill says: "In distant parts of the stellar regions, where the phenomena may be entirely unlike those with

which we are acquainted, it would be folly to affirm confidently that this general law [of causation, or causality] prevails, any more than those special ones which we have found to hold universally on our own planet. The uniformity in the succession of events, otherwise called the law of causation, must be received, not as a law of the universe, but of that portion of it only which is within the range of our means of sure observation, with a reasonable degree of extension to adjacent cases. To extend it further is to make a supposition without evidence, and to which, in the absence of any ground from experience for estimating its degree of probability, it would be idle to assign any.”⁵

Kant, and with him the *transcendentalists*, maintains that experience and induction can never lead to a knowledge which is strictly universal and necessary. “Experience teaches us, no doubt, that something is so or so, but not that it cannot be different. . . . Experience never imparts to its judgments true or strict, but only *assumed or relative, universality* (by means of induction), so that we ought always to say, so far as we have observed hitherto, there is no exception to this or that rule. If, therefore, a judgment is thought with strict universality, so that no exception is admitted as possible, it is not derived from experience, but valid absolutely *a priori*.”⁶ The strict necessity which we ascribe to inductive laws of science is the result of certain *a priori forms* of the mind and is not justifiable on the grounds of experience itself; it is due, therefore, to the peculiar constitution of the human mind which constructs such laws through the subjective force of the mind’s own nature. *Reid* and the Scottish School, on the

other hand, find the ultimate reason for the necessity of accepting inductive laws in an instinct of man's nature. The *pragmatists*, due to their theory of dynamic and fluent 'truth,' can see no absolute validity in the laws formulated by the inductive sciences; such laws have only provisional value.⁷

We maintain that induction is a valid process of inference, based on experience and observation. Experience and observation reveal facts which disclose to the intellect the nature or essence of a thing or property. Since this *nature* or *essence* is the *same in kind* for all members of a species or genus, the inductive law governing them will be truly universal and necessary. And if the law is grounded on some essential property or attribute common to all material things, the law will apply throughout the universe, even "in distant parts of the stellar regions," to all things at all times, past, present, and future, whether known or unknown, within and beyond the limits of actual observation.

THE TRUTH-VALUE OF INDUCTION

In order to avoid confusion of thought, it will be necessary to have a clear understanding of the meaning of 'essence' and 'nature' in this connection. The term is used in a threefold meaning. (1) We frequently designate by the term 'essence' anything, attribute, quality, or property, considered in the *abstract*, i.e., divested of all individualizing traits and characteristics. For example, 'humanity,' 'rationality,' 'roundness,' 'redness.' It was used

in this sense when discussing the problem of the universals. This is 'essence' in a wider sense. (2) It may also mean those attributes, qualities, and properties which are *invariably present* in a being, so that a necessary relation exists between them and the being which possesses them. They are 'essential' in opposition to 'accidental' attributes, qualities, and properties, in as much as the latter may be present or absent without affecting a being as to its species or genus. Whatever belongs to the 'essence' in this sense is either a *constitutive* element of the thing's being or *proceeds necessarily* from such a constitutive element. Whatever determines the genus, species, or specific difference of a thing, is a constitutive element of it; for instance, 'rationality,' 'humanity,' 'animality,' 'life,' 'materiality,' and 'substantiality,' in man. But that which flows or proceeds necessarily from such constitutive elements, is an essential property of the thing; such is 'the faculty of speech,' 'the power to laugh,' 'the capability to use tools,' etc., in man. This is 'essence' in a *strict* sense. (3) Finally, it may be taken to designate the *constitutive elements alone*, and not the properties which proceed necessarily from them. In this use of the term 'the faculty of speech,' 'the power to laugh,' etc., do not belong to the 'essence' of man. Here 'essence' is taken in its *strictest* sense. While science endeavors to discover the essence of things in the last meaning of the term, this is usually so difficult of attainment, that it must be satisfied in most cases with 'essence' in the *strict* sense. The *nature* of a thing is its essence considered as the principle of its activities.

We must now inquire into the *validity* of induction as a legitimate logical inference. Induction certainly seems to violate the canons of correct thinking, by passing from the truth of a *few* observed cases to a *universal* law which is supposed to apply to all cases of this kind. The conclusion (the universal law) is apparently much wider than the premises (the observed cases) from which it is drawn; and this looks suspiciously like an 'illicit process.' If this charge of an illicit process cannot be shown to be false, induction must be rejected. On what *grounds*, then, are we justified, after investigating a few observed instances, to formulate a universal law? When we examine a case of induction, we will perceive why we are obliged to consider it a valid inferential process.

In combining hydrogen and chlorine, for example, it is noticed that their quantities will not unite in any and all proportions. They combine in no other proportions than 1 to 35.5 by weight, or in other words, 1 to 1 by volume. These proportions are absolutely fixed and stable, no matter how the circumstances are varied. Having discovered this fact by induction, science enunciates the *law* that hydrochloric acid is formed by combining hydrogen and chlorine in the proportions of 1 to 35.5 by weight or 1 to 1 by volume. And this is a *universal law*, valid for all cases, at all times, and under all considerations. Whenever and wherever the experiment is made, the law is verified. And yet, whence comes the *universality* and *necessity* which we perceive to exist in this and other laws?

In the example just given we notice that the discovery of the general law is not the result of anything like a *complete*

enumeration of all possible quantities of hydrogen and chlorine in all possible combinations and circumstances. Scientists could not and do not attempt the impossible process of a complete enumeration. This universal law is the result of an *abstraction*. We perceive clearly that there must be a *sufficient reason* for this constant and invariable effect; and this reason cannot be anything like chance coincidence, but must be based on a definite, constantly and invariably operating *cause*. Now, there is only one thing that is constantly and invariably present in all these instances and experiments — the nature and essence of hydrogen and chlorine; the *nature* and *essence* of these elements is the cause, and the phenomena observed are the effect. Observations and experiments are made in such number and under such varying conditions until the mind clearly perceives that it is not only the nature of *this* hydrogen and *this* chlorine to form hydrochloric acid in these definite proportions, but that it is the nature and essence of hydrogen *as such* and of chlorine *as such* to produce these constant and invariable effects. We, therefore, prescind from the *particular* natures and essences observed in these few cases and penetrate by abstraction to the *nature and essence in general* of hydrogen and chlorine. Once this stage has been reached, there is no need of further experiments; since the nature and essence of hydrogen and chlorine will always remain the same in all conditions of time and place (for they never can be anything but hydrogen and chlorine), they will produce the same effects always and everywhere. This being certain, this conclusion is expressed in a universal

law; and the law can now be applied without fail to every instance which may arise in the world or in the laboratory. Science has been increased by a new law, and the mind has been enriched by a new truth.

The relation of the inductive *law* to the individual *phenomena* parallels the relation of the universal idea to the individual *things*. Both are the result of the abstractive power of the intellect, leaving aside the individuating differences and grasping the nature or essence common to them all. Thereby the idea and the law become *abstract, necessary, and universal*, applicable to the whole class as a class and to every single member of the class, irrespective of time or place. It is precisely this necessary and universal character of the idea and the law which makes them valuable for science and philosophy and constitutes a distinct advance of human knowledge. Scientific laws are expressed in definite categorical statements; and truth, as we know, is only found in categorical judgments which are an actual representation of reality as it is. The laws of science, discovered through induction, are, therefore, not mere figments of the thinking mind, as Kant claims, nor mere empiric generalizations of great probability, as the empiricists assert, nor general statements of provisional value, as pragmatists maintain, but genuinely *universal laws* expressive of reality.

Such is the nature of induction. The instance of the formation of hydrochloric acid is given merely as an illustration of the inductive process as used in every department of science. The details of method will vary, of course, according to the individual problems to be solved,

but the fundamental principles of procedure are the same: it is an *abstraction*, passing from the particular to the universal, from the effect to the cause, from the logical part to the logical whole, from the phenomena to the law.

If we now sum up the *underlying principles* of induction, they will be seen to be as follows: (1) Any attribute, quality, or property which, no matter how the external conditions are varied, is found to belong constantly and invariably to a certain thing, must have a *constant* and *intrinsic* reason for itself *in* that thing; and any effect which is constantly and invariably produced by a certain thing, must proceed from a *constant* and *intrinsic* cause in that thing. (2) Whatever is constant and intrinsic in a thing is either its essence and nature or a direct result of its essence and nature, because this nature and essence is the only reality which is constantly and intrinsically in the thing, everything else being accidental and subject to change. (3) Whatever pertains directly to the essence and nature of a thing must be found *in every individual* who possesses such an essence and nature.⁸ Since, then, the inferential force of induction does not rest on a complete enumeration of all individual instances, but is grounded on the 'nature' and essence of the *beings as such*, it is evident that induction does not involve an illicit process. On the contrary, the logical grounds are perfectly legitimate and adequate for the formulation of universal laws. Science, therefore, is justified in using induction as an instrument for discovering and establishing physical laws, and these laws reveal new truths and extend human knowledge.

Hence, both deduction and induction are *valid processes of reasoning*, leading to a true interpretation of reality. The objections raised against their validity are seen to be without foundation, and human reason as a source of true and valid knowledge is vindicated. This, of course, has always been a spontaneous conviction of mankind, and the critical examination of our intellectual operations has shown conclusively that this conviction is warranted and correct.

SUMMARY OF CHAPTER XVIII

Mediate knowledge is acquired by means of *reasoning*, or ratiocination. When we argue from the truth of the logical whole to that of the logical part, we have *deduction*; when we argue from the truth of the logical parts to that of the logical whole, we have *induction*. Serious objections have been raised against both as a legitimate inference.

1. *The Problem of Deduction.* Empiricists and positivists charge that deduction involves a begging of the question. The major premise is a general statement whose truth *presupposes* the truth of each particular instance comprised within the extension of the general statement; hence, the conclusion is already known before the general statement can be made. So Mill.

2. *The Truth-Value of Deduction.* Mill admits that the major premise is a general statement whose truth is discovered by induction. He also admits that such a general statement is derived from the observation of a limited number of instances, yet it is valid for 'all similar instances, past, present, and future.' But this proves that all individual instances need not have been previously known in order to make the general statement a valid major premise in a syllogism; hence, Mill is wrong when he asserts that the conclusion must already be known in the major premise. The conclusion is contained *virtually* in the major premise, but not *formally*; and it is only formal knowledge which is actual knowledge. Consequently, deduction can give us new knowledge by means of a legitimate inference. Besides,

many important scientific discoveries have been made through deduction, especially in mathematics and astronomy.

3. *The Problem of Induction.* Induction is complete when it consists of a mere totalization of the individual instances. It is *incomplete* and *scientific*, when it is based on a limited number of instances and from these infers the constant and necessary relations existing between things and between the properties of things. It leads to a *universal law*. This, however, seems to involve an illicit process, because the law is apparently an inference from the truth of 'some' to the truth of 'all.' *Empiricists* will not admit certitude for scientific induction beyond the limits of observation. *Kant* and the transcendentalists will not admit a true and strict, but only an assumed and relative, universality for the law. *Pragmatists* consider inductive laws to have only provisional value. We maintain that induction is based on the nature and essence of the observed things and is, therefore, an inference valid beyond the limits of observation and truly universal.

4. *The Truth-Value of induction.* What are the logical grounds for the universal validity of induction? It is not a complete enumeration of all instances, because such an enumeration is impossible. It is based on *abstraction*. The only sufficient reason for the constancy and invariability of natural effects is observed by the intellect to lie in the nature and essence of the things observed. From this we conclude that it lies in their *nature* and *essence* as such to produce these effects. Consequently, wherever and whenever this nature and essence is present, it will produce

these effects. This, then, is the sufficient reason for the universality and necessity expressed in the law.

Deduction and induction are, therefore, valid forms of reasoning, and reasoning is critically justified.

Chapter 19

RECAPITULATION

IT IS THE PURPOSE OF EPISTEMOLOGY TO EXAMINE THE RATIONAL grounds upon which our spontaneous convictions are based, in order to see whether they are philosophically justified. This involves an investigation into the *validity*, or truth-value, of human knowledge; and that in turn involves an investigation into the reliability of the *sources* of our knowledge. These sources are the faculties which furnish the data from which knowledge is derived, and these sources are: consciousness, sense-perception, and intellection. It is characteristic of human knowledge that it claims to be a true representation or interpretation of *reality as it is*, not merely a subjective construction of the mind; and man has the spontaneous conviction that his knowledge actually conforms to extra-mental reality and as such is valid and true.

This, however, is not so simple as it seems. All knowledge is a mental state and therefore subjective; apparently, then, knowledge has only subjective value. Knowledge is fashioned from ideas; what, then, can the mind know but its own ideas? Again, how can extended bodies make an impression on an unextended mind, or how can an

unextended mind know extended bodies? There appears to be no common ground between mind and matter.

Ever since the days of Descartes the problem of knowledge has been acute. He inaugurated the modern epistemological problem by introducing an *excessive psycho-physical dualism* between mind and matter, soul and body. These realities are so disparate and antithetical in nature that a contact between them is utterly impossible. It followed with necessity that the mind could not effect a cognitional union between itself and extra-mental reality; the mind could not transcend itself and know the world, and an impassable gulf was placed between them. Either a bridge had to be found to span the intervening distance, or our knowledge of the world is an illusion. In his attempt to explain man's knowledge of his own body and of the world at large, Descartes had recourse to the theory of *innate ideas*: our knowledge is inborn and gradually unfolds itself out of the depths of the mind. Man, then, can know nothing but his own ideas and the internal states within himself; such was the inevitable consequence of his theory of innatism. The capital error of Descartes consisted in his overlooking the fact that man is a unit: body and soul (mind) form a *single psycho-physical organism*.

It was to be expected that subsequent philosophers would not be satisfied with Descartes' theory of innate ideas, and so different systems arose in an endeavor to give a more rational account of our obvious knowledge of the world around us. But practically all accepted the apparently evident principle that the mind can know nothing but its own states. The result was philosophical chaos. Theories

succeeded theories in kaleidoscopic confusion. They showed a double trend: if they followed the *mechanistic* body side of Descartes' views, they developed into empiricism, positivism, materialism, and skepticism; if they followed the *spiritualistic* mind-side of his theory, they branched off into ontologism, transcendentalism, and monistic idealism. And thus the excessive dualism of Descartes was reduced to absurdity.

A reaction toward the *common-sense view of realism* was inevitable; all humanity could not be so radically wrong, otherwise true knowledge must be adjudged impossible of attainment. The twentieth century witnessed the return of a saner outlook in the rise of pragmatism, neo-realism, and critical realism. Slowly the pendulum is swinging back to the aristotelianism of the scholastics as the only rational explanation of human knowledge. Philosophers realize at last that the 'idealist postulate,' maintaining that the mind is restricted in its knowledge to its own subjective states, is based on fallacy: *the mind of man can transcend itself* and contact the external world in cognition. The most recent epistemological theories defend some sort of *presentative realism* as the natural explanation of man's knowledge. That they do not succeed completely in their efforts to expound an all-round satisfactory system, is the result of their materialistic and evolutionistic tendencies; and they will never succeed until they come to the scientific and philosophic conclusion that body and mind, though essentially different as physical and psychical entities, are bound together as part-principles of a *psycho-physical organism* in the higher unity of the *Ego*. The

animated body is the *epistemological bridge* between the mind and the world. Therein lies the solution of the problem of human knowledge.

Strictly speaking, it is not the function of epistemology to explain the 'nature' of the knowing subject; that belongs to the province of psychology. Nevertheless, a careful examination of the data of knowledge points clearly to certain definite conclusions. The data of *consciousness* show that mind and body are constituent parts of the Ego; the Ego is an abiding reality, the ultimate possessor of mental and bodily states. The data of *sense-perception* reveal the indubitable fact that we can and do perceive extra-mental reality in our body and extra-Ego reality in the bodies existing in the external world. This cannot be denied without destroying the foundations of our knowledge. Neither idealism nor representative realism gives an adequate explanation of our knowledge, as manifested in sense-perception; *presentative realism* alone can account for the facts. If we analyze the data, we find that sense-perception is neither a purely mental function nor a purely bodily operation, but an activity which involves the presence of both physical and psychical elements; it is 'extended,' but 'vital,' and as such can proceed only from a psycho-physical base; in other words, an *animated organism* is demanded, if we wish to give a rational account of the process of knowledge as manifested in sense-perception. Any other theory will either necessitate the reduction of the mind to matter (materialism), or the sublimation of matter to mind (idealism), or the complete severance of mind and matter (Cartesian dualism); the first

cannot explain our intellectual knowledge, the second cannot explain our sense-knowledge, and the third cannot explain the combination of both. In order to explain the existence and validity of intellectual knowledge and sense-knowledge in man, man must be a unitary being capable of sense-perception and of intellection; and that means that he is an organism, a 'rational animal,' consisting of a vital body and a rational mind.

Our investigation into the data of consciousness, sense-perception, and intellection has shown that our knowledge in these fields is *essentially valid and true*. Errors occur, but they are incidental and accidental. As a general conclusion, then, the spontaneous convictions of man regarding the nature and scope of his knowledge have been critically vindicated. These convictions can no longer be considered unwarranted assumptions; they have now become reflex and philosophical certainties. We have the reasoned and critical assurance that our faculties of knowledge are essentially reliable and give us a truthful interpretation of 'reality as it is'; the information we receive through them is not complete and exhaustive, but it is true and valid as far as they can reach. And that is all that we can expect.

The validity, or truth-value, of human knowledge has been established after a careful scrutiny of the evidence. The 'process' of knowing is still mysterious and obscure; but the 'fact' of its validity should no longer be in doubt. That our solution agrees with the aristotelian-scholastic solution of the problem of knowledge, is simply due to the reason that no other theory will explain the acknowledged data in a satisfactory manner. It alone is capable of giving an

intelligible explanation of the cognitional union between reality and the mind.

GLOSSARY OF TERMS

NOTE: In the case of qualified words, always look for the word or noun qualified. For example: in seeking for *Epistemological Monism*, look for *Monism*, *Epistemological*, etc.

ABSOLUTE. The unconditioned, the ultimate ground of all reality.

ABSOLUTISM, EPISTEMOLOGICAL. See Idealism, Absolute.

ACOSMISM. The doctrine which denies or doubts the validity of our experiential knowledge concerning the existence and reality of a material world; immaterialism.

AGNOSTICISM. The doctrine which denies the constitutional ability of the mind to know reality and concludes

with the recognition of an intrinsically Unknowable.

ARISTOTELIANISM. The system of thought which in general follows the principles and teachings of Aristotle. Peripateticism.

ASSOCIATIONISM. In the problem of necessary judgments, the doctrine which holds that the necessity of

first principles is due to the law of associations as a form of mental compulsion.

CERTITUDE. That mental state in which the mind gives a firm assent to a judgment without fear of the possibility of error, due to recognized valid reasons.

COHERENCE. Coherence, or consistency, with the whole system of knowledge previously recognized as true, is considered by idealistic monism to be the criterion of truth.

CONCEPTUALISM. The doctrine which holds that we have universal ideas in the mind, but there is no objective ground or foundation in extra-mental objects which would entitle the mind to group a number of individuals under one (universal) idea.

CONSCIOUSNESS. The intuitive awareness by which we recognize something as cognitively present in the mind.

CONVICTIONS, SPONTANEOUS. Common-sense or ordinary convictions which have not been subjected to a critical investigation.

CRITERIOLOGY. The Science of the criteria or tests of truth. Frequently used synonymously of epistemology.

CRITERION. The test by which we distinguish true judgments from those which are false.

DEFINITION BY INITIAL PREDICATION. See Predication.

DOGMATISM, CRITICAL. The doctrine which, after a critical examination, accepts the three primary truths as essentially necessary for every process of thinking and reasoning prior to the investigation of the various classes of spontaneous convictions.

DOGMATISM, MITIGATED. The form of dogmatism which accepts only two facts as prerequisites for the solution of the problem of certitude, namely, the existence of necessary spontaneous assents (convictions) and the power to examine these by reflection.

DUALISM. The theory that physical objects are independent in their existence and nature from the mental act of perception and knowledge; that there is an essential distinction between 'mental' and 'real' objects and events, so that the latter exist irrespective of whether known or not known by a perceiver.

DUALISM, EPISTEMOLOGICAL. The theory that there exists a duality or non-identity between the content or datum, which is immediately and indubitably presented in the knowledge act at a given moment, and the reality or object known through the content or datum.

EGO. The human person, considered as possessing a body and mind; the subject of all psychical states, such as perception, thought, judgment, affective and volitional states; self.

EGO, ABSOLUTE. The non-individual, pure Ego, neither subject nor object, which posits the world.

EMERGENT EVOLUTION. See Evolution, Emergent.

EMPIRICISM. The doctrine which denies or doubts the validity of all intellectual knowledge and admits only the certainty of sense-knowledge.

EPISTEMOLOGY. The science of the validity, or truth-value, of knowledge. ERROR. Disconformity between mind and thing.

EVIDENCE, OBJECTIVE. That characteristic of reality whereby it becomes objectively manifest to the perceiving faculty.

EVOLUTION, EMERGENT. The doctrine which holds that nature is the product of evolution in such a manner that entirely new and unpredictable properties originate through synthesis and thereby form new and higher levels of reality.

EVOLUTIONISM, In the problem of necessary judgments, it is the doctrine which holds that the necessity of these judgments is due to certain fixed forms of thought which have been engendered in the past history of the human race and have been transmitted by heredity through a process of neural association repeated with countless frequency.

FICTIONALISM. The doctrine which holds that all concepts are fictions of the mind and have fictional value as mental constructions of reality, though they need not be true in themselves.

FIDEISM. The traditional doctrine which holds that all our knowledge must begin with an act of faith in divine revelation, since human reason is impotent to arrive at any certitude regarding the fundamental truths necessary for man to know; also, the doctrine that such truths can be known only by an affective act of faith.

FORMALISM. In the problem of necessary judgments, the theory which holds that the necessity of judgments is due to native a priori mental forms.

HUMANISM. See Pragmatism.

HYLOPSYCHISM. The doctrine which holds that all matter is instinct with something of the cognitive function; that every objective event has that self-transcending implication of other events which, when it occurs on the scale that it does in our brain processes, we call consciousness.

IDEA. (1) A mental representation of a thing. (2) Platonic Idea: an archetype, or pure immaterial pattern, of which the individual objects in any one natural class are but the imperfect copies, and by participation in which they have their being. (3) Descartes and English philosophers: an immediate object of consciousness.

IDEALISM. In general, the doctrine which holds that the being of things is conditioned by their being known; consciousness is constitutive of its objects; the being of sensible things is simply their being sensed, and their true characters are their sensed characters; the world we know is the world of our perceptual content; the mind cannot transcend its own internal, conscious states.

IDEALISM, ABSOLUTE. The doctrine that the relativity of knowledge implies the subjectivity of the objects of knowledge, so that the universe and everything in it are merely states of the thinker's mind; the real and the ideal, thought and thing, nature and spirit, object and subject, world and mind, are ultimately identified in the infinite and absolute Ego.

IDEALISM, COSMOTHEITICAL. The doctrine which holds that the external world exists, but that we have no

immediate knowledge of it.

IDEALISM, DIALECTICAL. See Idealism, Logical.

IDEALISM, EPISTEMOLOGICAL. The doctrine which holds that the external world has no existence independent of consciousness, but exists as an object of possible experience, as the content of universal experience, or as the content of a knowing mind, as something immanent to consciousness.

IDEALISM, LOGICAL. The doctrine which holds that reality is constituted of logical ideas (logical entities), so that we have direct knowledge of reality in the ideas of logical thought.

IDEALISM, METAPHYSICAL. The doctrine which holds that the real is identical with idea and mind, and the objects are modifications and evolutionary modes of the one, self-existent, absolute consciousness.

IDEALISM, OBJECTIVE. The doctrine which holds that the relation between the subject and the object of thought is one of absolute identity, supposing that all things exist in the absolute reason and that the laws of physics are the same as those of mental representations.

IDEALISM, PSYCHOLOGICAL. The doctrine which holds that the physical object is essentially idea, in the sense of being simply a part of consciousness, a content of conscious life which depends upon consciousness for its existence or at least upon the conscious relation to some subject.

IDEALISM, SUBJECTIVE. The doctrine which holds that the universal subject or Ego (not the Ego of the individual person) is the source of the object, the external world, or non-Ego.

IDEALISM, TRANSCENDENTAL. The doctrine that the mind imposes its own a priori forms of synthesis upon the unorganized and unrelated impressions which it receives from an unknown and unknowable thing-in-itself, or noumenon, so that the entire content of perception and thought consists of subjective phenomena.

IDEAL-REALISM. A metaphysical doctrine which combines the principles of idealism and realism.

IMAGINISM. An idealistic doctrine which holds that the world-principle resembles the imagining with which we humans are directly acquainted, and this cosmic imagining is a conscious infinite activity and the creative force of all reality.

IMMATERIALISM. The doctrine which denies or doubts the existence of material reality, admitting nothing but the reality of immaterial or spiritual things; that particular form of skepticism which admits the certitude of intellectual knowledge only, doubting or denying the validity of experiential knowledge; acosmism.

INCONCEIVABILITY. The inconceivability of the contradictory judgment is considered by some philosophers to be the ultimate criterion of truth.

INSTRUMENTALISM. The doctrine which holds that ideas are instruments of action and that their usefulness determines their truth.

MATERIALISM. A naturalistic form of philosophy which finds the ultimate solution of all phenomena, physical and psychical, in the nature and activity of universal matter or force.

MIND. In epistemology, the conscious knowing subject or the conscious knowing part of the subject.

MONADISM. The Leibnitzian doctrine which holds that the ultimate individual beings are monads; they are partly material and partly immaterial, possess innate power of representation, have no means of cognitional intercommunication, and obtain knowledge corresponding to reality through a divinely pre-established harmony.

MONISM. The doctrine which seeks to deduce all the varied phenomena of both the physical and spiritual worlds from a single principle which is in a continuous state of evolution; specifically, the metaphysical doctrine which holds that there is but one substance, either mind (idealism), or matter (materialism), or a neutral substance that is neither mind nor matter but is the substantial ground of both: opposed to dualism and pluralism.

MONISM, EPISTEMOLOGICAL. The doctrine which holds that the content or datum of perception is identical with the reality or object known thereby; that the attributes of the percept as experienced and all its relations, except that of being experienced, are identical with the entities composing the physical world; there is no dualism of things and ideas, but only the class of things.

MOTIVE OF CERTITUDE. The ground or reason which determines us to assent with firmness to a judgment as true without fear of its contradictory being true.

NATURALISM. The doctrine that scientific knowledge of physical objects is the final and only legitimate form of knowledge.

NEO-HEGELIANISM. See Neo-Idealism.

NEO-IDEALISM. A more recent form of Absolute Idealism, characterized by an approach to the problem of knowledge through experience rather than by means of aprioristic speculations; neo-hegelianism.

NEO-PSYCHOLOGISM. A more recent form of psychological idealism, characterized by a closer union between empirical science and psychology.

NEO-REALISM. The doctrine which holds that there are existent objects not conditioned by perception or cognition; all the attributes of the percept as experienced and all its relations, except that of being experienced, independently characterize such objects; pan-objectivism.

NEO-SCHOLASTICISM. The system of philosophy which in the main follows the principles and tenets of scholasticism, but adapts it to modern problems.

NOMINALISM. The doctrine which holds that there are neither universal objects outside the mind nor universal ideas in the mind.

NON-EGO. Not-self; the whole world, distinct from man's body and mind and outside his person, as something other-than-self.

NOUMENON. The unknowable reality or thing-in-itself which is postulated as the basis, ground, or cause of the phenomenon.

OBJECT. In epistemology, the thing known.

OBJECTIVISM. The doctrine that things are, when not experienced by us, just what they seem when experienced by us.

OCCASIONALISM. The doctrine which holds that cognition is caused by the sole activity of the mind on the occasion of bodily stimuli; in a special sense, the doctrine which holds that God is the cause of knowledge in the human mind on the occasion of bodily stimuli and also the cause of all actions in bodies.

ONTOLOGISM. The doctrine which holds that man's mind derives all its knowledge through a direct, immediate intuition of God's ideas or of absolute Being.

PANCALISM. A form of esthetic pragmatism.

PAN-EGOISM. The doctrine which attempts to dissolve the antithesis between noumenon and phenomenon, mind and matter, Ego and thing-in-itself, by identifying all reality with the universal consciousness or Ego; a form of absolute idealism, asserting the one-ness of all things in the absolute Ego.

PAN-OBJECTIVISM. See Neo-realism.

PAN-PHENOMENALISM. The doctrine which holds that the human mind can know nothing but the phenomena or appearances of things.

PAN-PSYCHISM. The doctrine which interprets the qualitative essence of material force and energy as a sort of psychical activity and appetency, so that all material reality, in its ultimate analysis, is endowed with psychical powers.

PANTHEISM. The doctrine which holds that the universe is identical with God; the reduction of God to the universe, or of the universe to God.

PARALLELISM, PSYCHO-PHYSICAL. The doctrine which holds that mind and matter are not substances, that the

psychical and physical are but a manifold of interrelated occurrences; subject and object are concepts which are due to the reflection resulting from the interrelations of the various components of the absolutely unitary contents of our immediate experience.

PERCEPTIONISM. See Realism, Presentative.

PERIPATETICISM. See Aristotelianism.

PERSONALISM. That form of idealism which gives equal recognition to both the pluralistic and monistic aspects of experience and which finds in the conscious unity, identity, and free activity of personality the key to the nature of reality and the solution of the ultimate problems of philosophy.

PHENOMENALISM. The doctrine that the appearances of things are their reality; there are no things in themselves, but only things in relation to our experience.

PHENOMENON. In epistemology, the appearance that is produced by the action of a thing upon a percipient.

PLURALISM. The doctrine which holds that reality cannot be reduced to either one ultimate form of being (monism of either mind or matter) or two ultimate forms of being (dualism of mind and matter), but to many mutually irreducible ultimate forms of being.

POSITIVISM. A form of naturalism which denies the legitimacy of philosophical problems and methods and claims that science is the only knowledge which is exact and ultimate.

POSTULATE, IDEALIST. The postulate, or axiom, considered by idealists as self-evident, that all objects of knowledge are mental objects, ideas, conscious states.

PRAGMATISM. The doctrine, or rather attitude, which places all knowledge and truth in a direct relation to life and action; it judges the value of ideas, judgments, hypotheses, theories, and systems, according to their capacity to satisfy human needs and interests in a social way.

PREDICAMENT, EGO-CENTRIC. The predicament involved in every act of knowledge that no thinker is able to mention a thing that is not an idea, for the obvious and simple reason that in mentioning it he makes it an idea; it is, therefore, impossible to discover whether the cognitive relationship is indispensable to things which enter into it.

PREDICATION, DEFINITION BY INITIAL. The fallacy which consists in considering an 'obvious' characteristic of a thing as the exclusive' characteristic of that thing, and then defines the thing as consisting solely and exclusively of this particular characteristic.

RATIONALISM. The method of proving propositions by appealing to abstract and universal principles.

REALISM. In general, the doctrine which holds that objects have an existence independent of their being known so that their relation to the subject in knowledge is only an external, not an internal or immanent, relation.

REALISM, ARISTOTELIAN-THOMISTIC. The doctrine which holds that man does not infer the existence of external objects from representative images or 'ideas' in consciousness, but perceives them directly in some form through a presentation of the objects themselves in sense-perception.

REALISM, COSMOTHETICAL. See Realism, Representative.

REALISM, CRITICAL. The doctrine which holds that we know physical objects by means of, and in terms of, logical ideas, but that it is the external object which we know and to which this complex act of cognition is directed; what we perceive is existentially identical with the independent reality, but it has, when being perceived, certain qualities — notably the sense qualities — which it does not possess when not perceived.

REALISM, CRITICAL PRESENTATIVE. That form of presentative realism which holds that some qualities of objects are real and as such are perceived immediately, while others are not actually and formally, but only potentially and causally, present in the objects; these latter have no formal existence independent of the perceiving subject. Also called moderate presentative realism.

REALISM, EPISTEMOLOGICAL. The theory that the real object has an existence independent of the experient's perception and thought.

REALISM, HYPOTHETICAL. See Realism, Representative.

REALISM, IMMEDIATE. See Realism, Presentative.

REALISM, INFERENTIAL. See Realism, Representative.

REALISM, INTUITIVE. See Realism, Presentative.

REALISM, MEDIATE. See Realism, Representative.

REALISM, MODERATE. In the problem of the universals, it is the doctrine which holds that there are no universal realities outside the mind, but we have universal ideas in the mind, and there is a foundation in the things themselves

for these universal ideas; universals are formally in the mind, but fundamentally in the things.

REALISM, MODERATE PRESENTATIVE. See Realism, Critical Presentative.

REALISM, NAÏVE PRESENTATIVE. See Realism, Rigid Presentative.

REALISM, NATURAL. See Realism, Presentative.

REALISM, NEW. See Neo-Realism.

REALISM, OBJECTIVE REPRESENTATIVE. That form of representative realism which holds that our 'representations' or 'ideas' resemble the external objects.

REALISM, PRESENTATIVE. The doctrine which holds that physical, external objects are presented directly in some form to consciousness in sense-perception, so that their reality is perceived as it exists 'out here' in nature. Also called immediate, intuitive, natural realism or perceptionism.

REALISM, REPRESENTATIVE. The doctrine which holds that the human mind is immediately aware, not of the external objects themselves, but of its own internal 'representations' or 'ideas' only, from which it then infers the external, non-Ego reality as their cause. Also called mediate, hypothetical, cosmothetical, inferential realism.

REALISM, RIGID PRESENTATIVE. That form of presentative realism which holds that the things perceived are actually so in nature as they appear to the senses. Also called naïve presentative realism.

REALISM, SUBJECTIVE REPRESENTATIVE. That form of representative realism which holds that our

‘representations’ or ‘ideas’ do not resemble the external objects.

REALISM, TRANSFIGURED. The doctrine which holds that the reality underlying appearances is totally and forever inconceivable to us; we know only appearances (phenomena) of reality and in them reality is transfigured or altered to such an extent that there is no resemblance between reality and the perceptual knowledge we have of it; Spencer’s subjective representative realism.

RELATIVISM. The doctrine that every known object is relative (in relation) to the knowing subject and as such is dependent in its being upon the knowing subject and incapable of existing apart from consciousness; the doctrine of the immanence of relations as constitutive of their being.

RELATIVISM, OBJECTIVE. The doctrine that the existence and character of experienced data depend upon the occurrence of percipient events and therefore upon the nature and situation of the experiencing organism as their essential and proximately determining factor; that the object known possesses the character exhibited by the datum only ‘in relation to’ this given organism; and that the perceptual content is ‘objectively’ present in nature precisely as experienced in perception and cognition, according to the relative standpoint of the individual perceiver.

REPRESENTATIONALISM. See Realism, Representative.

SCHOLASTICISM. The system of philosophy, prevalent in the middle ages, which follows the general lines of Aristotle’s principles. It advocates a natural dualism of God

and creature, mind and matter, thought and thing, as against monism and pantheism; it defends a moderate realism, as against ultra-realism, nominalism and conceptualism; it is spiritualistic and not materialistic, experimental and not aprioristic, objectivistic and not subjectivistic; in sense-perception it is presentational and not agnostic or representational or idealistic; concerning intellectual knowledge it defends a moderate rationalism, as against sensism, positivism, and innatism; it is common-sense knowledge critically examined and philosophically vindicated.

SELF-CONSCIOUSNESS. Reflex consciousness, by means of which the Ego apprehends itself concretely in its own mental acts and states; self-awareness.

SENSATIONALISM. The doctrine which holds that sensation is the sole origin of knowledge.

SENSISM. See Sensationalism.

SKEPTICISM. The reasoning of one who doubts the possibility of knowledge of reality; the systematic doubt which characterizes a philosophic skeptic.

SKEPTICISM, ABSOLUTE. The absence of any leaning toward either side of any question, when maintained as a philosophic principle.

SKEPTICISM, PYRRHONIC. See Skepticism, Absolute.

SOLIPSISM. The skeptical attitude, in which the thinker is certain only of his own personal internal states of mind.

SPINOZISM. The doctrine of Baruch Spinoza which holds that there exists but a single substance, infinite and uncreated, of which nature (matter) and thought (mind) are

the attributes; it is a pantheistic, absolute, metaphysical monism.

SUBJECT. In epistemology, that which possesses knowledge, perception, thought, consciousness; the mind, in so far as it possesses internal states of knowledge; the knower.

SUBJECTIVISM. The doctrine which holds that we can immediately know only what is present in consciousness.

TRADITIONALISM. The doctrine which holds that God gave a primitive revelation to mankind which is handed down as a tradition from generation to generation, and this tradition is the ultimate foundation of knowledge and criterion of truth.

TRANSCENDENCE. The characteristic of human knowledge enabling the mind to pass beyond the limits of its own internal state and to know extra-mental reality.

TRUTH. Conformity between mind and thing.

TRUTHS, PRIMARY. The First Fact: my own existence — 'I exist.' The First Principle: the Principle of Contradiction — 'It is impossible for a thing to be and not to be at the same time.' The First Condition: the essential trustworthiness of reason — 'Reason is capable of knowing truth.'

ULTRA-MECHANISM. The doctrine which excludes the human body as an essential participant in the vital functions of man, so that the body is considered to be actuated solely by mechanical forces.

ULTRA-REALISM. The doctrine which holds that we have not only universal ideas in the mind, but that there exist extra-mental universal realities corresponding to them.

ULTRA-SPIRITUALISM. The doctrine which postulates an excessive dualism between mind (soul) and body in the human Ego, destroying the conception of man as an organism, so that a cognitional communication between them is impossible.

UNIVERSAL. An idea, the content of which is predicable of a class as a class and of each individual member of a class.

AUTHOR'S PREFACE

THIS IS a book of acquaintance. As a rule, college students and general readers have had little or no acquaintance with ontology, or general metaphysics, as a science in its own right. Many ideas of an ontological or metaphysical character are, of course, encountered in their daily reading in books, magazine articles, scientific treatises, and professional discussions of all kinds. While the general meaning of such ideas is clear enough, their signification and implication, as an integral part in the structure of philosophic thought, is unknown or hardly felt. They become understood and appreciated in their full value only when studied in the context of the philosophic science of ontology or metaphysics as a whole. Hence the need of correlating these scattered ideas into a basic science, such as ontology, and of fitting them into the fundamental framework of a philosophic system of thought.

It is hoped that this book may be helpful to the student and general reader in accomplishing this purpose. It is primarily a student's book, written from the standpoint of the student's mentality and educational development. While a general education, as a preparatory stage of mental

culture, is presupposed, no special previous acquaintance with the subject matter of ontology is expected or demanded.

In accordance with this purpose, the scope of the book is frankly positive and constructive. It attempts to build up an understanding of the matter of ontology in a logical manner, using simple language, illustrating the subjects with copious examples, and extracting the contents of each chapter into compact summaries. Some of the more abstruse problems of ontology, such as the problem of essence and existence, have been omitted; it was felt that the average student would derive little benefit from a lengthy discussion of problems which have taxed the ingenuity and acumen of the most profound intellects. Such problems may be attacked after the student has become acquainted with the ideas and subjects which form the foundation of the science of metaphysics. After all, the student cannot be expected to be a professional philosopher; it should be sufficient if he acquires a thorough grounding in fundamentals, so that he can deepen his knowledge through subsequent reading and study.

It might seem at times that the author is belaboring the obvious. However, one must bear in mind that the average student will not be clear in his ideas and principles until they are reduced to the simplest and most basic terms of evidence. Experience in the classroom proves this beyond dispute. The author, therefore, having the mental needs of the student always in view, has not hesitated to use this method whenever considered advisable. For the same reason, recapitulations of treated material are inserted at

various points throughout the book. The subject matter is complex and difficult at times, and the mind of the student may become confused through the multiplicity of details; a certain amount of periodic recapitulation should help the student to obtain a proper orientation as he proceeds on his way. The method and language of presentation is, generally speaking, comparatively non-mechanical; to have the student grasp the meaning of technical terms and ideas, one must speak the language of the student. While the sharpness and nicety of philosophical terminology will suffer somewhat for the time being, in the end the student will have acquired a technical vocabulary which should be fairly accurate and complete.

That the author's policy and method of presentation is essentially sound, is evidenced by the fact that his logic, *The Science of Correct Thinking*, and his epistemology, *Reality and the Mind*, have been adopted by a large number of colleges and universities as texts. It is hoped that this book will meet with similar favor and will render similar service.

THE AUTHOR

PART I

BEING AND ITS PRIMARY DETERMINATIONS

Chapter 1

SCIENCE, METAPHYSICS, ONTOLOGY

MAN'S MIND IS NEVER PERMANENTLY SATISFIED WITH A commonplace, obvious, and superficial knowledge of nature. It forever seeks to penetrate the veil of phenomena and to grasp the reality of things. This is due partly to man's insatiable craving for knowledge and partly to his desire to control the forces of nature. No doubt, the practical advantages resulting from such control furnish in most instances the original spur for knowledge; subsequently, however, knowledge for its own sake, for the mental satisfaction it affords, becomes a dominant factor in man's incessant search for the realities which make the wheels of the world go round. And with increased knowledge in widely separated fields comes the need to unify and systematize the scattered truths. Thus is science born.

SCIENCE

Science is not interested in isolated, individual facts and things, except in so far as they represent the traits of a class and of a law. A kettle of boiling water, a flash of lightning, a horseshoe magnet, a ray of sunshine, a sheaf of

wheat, a mongrel dog, an Australian bushman — these things mean little to the scientist when taken as individual facts. However, the laws of thermo-dynamics, of electricity, of magnetism, of light, of plant, animal, and human life, manifested by these things, are of great importance. If the scientist can discover the *causes* of such phenomena and the *laws* according to which they operate, he has acquired a knowledge which is the scientific explanation of the working forces of nature.

Each science has its own selected field of research. The material object may be the same for several sciences, but the formal object is different for each. By the *material* object of a science we understand the general object with which it occupies itself in its investigation; and by the *formal* object we understand that special phase or aspect of the general object which forms the subject matter peculiar to this science and which distinguishes it from all other sciences. The bodies existing in the world are the material object of the natural sciences; for instance, of astronomy, geology, physics, chemistry, biology, medicine, mathematics, etc. Each of these sciences, however, views and investigates bodies from its own peculiar standpoint. A particular class of bodies may be the material object of a number of special sciences. Organisms, or living bodies, are the material object of biology, botany, zoology, and anthropology; but while biology treats of life in general, botany treats of plants, zoology of animals, and anthropology of man.

While various sciences are engaged with the same bodies in general, it will be observed that each one examines them from a different standpoint. The fact,

however, that their material object is more or less common to them all, shows that no special science is completely isolated from the others. When compared to each other, certain features of reality will be found in them all. For example, all presuppose the existence of bodies, of quantity, quality, relation, cause and effect, relative permanence amid constant change, extension, mass, energy, and the like. Now, just as the single sciences are the result of the unifying and systematizing tendency of man's mind in particular fields of investigation, so the presence of such *common elements in all the sciences* entitles the mind to attempt a further unification and systematization of the various sciences in their more universal aspects, in order to harmonize their differences in a higher unity and synthesis of knowledge. And that, precisely, is the knowledge of *philosophy*.

The sciences seek the knowledge of things in their 'proximate' causes. *Philosophy*, on the other hand, is the science of things in their *ultimate causes, reasons, and principles*, acquired by the aid of human reason alone. It endeavors to obtain a more definite, extensive, scientific knowledge of those realities which are the *foundation* of the special sciences and which they accept as granted without previous investigation or proof. That leads us to metaphysics.

METAPHYSICS

The term 'metaphysics' had a peculiar origin. It was coined by *Andronicus of Rhodes* (about 70 B.C.); but the meaning

now universally associated with it hardly entered his mind. What he called *μετα τα φυσικα* meant only 'that which follows after physics,' in as much as he, when he edited Aristotle's works, placed this particular department of philosophy *after* the parts which followed Aristotle's discourse on physical nature. The term thus had only a systematic value. *Aristotle* (384—322 B.C.) himself called this part of his philosophy 'the theological science,' because it led up to a consideration of God and His attributes; and he also styled it 'the first philosophy,' since it treated of first or fundamental causes which, in his opinion, furnished us with knowledge of prime importance. Due to the curious coincidence that this 'first philosophy' of Aristotle treated of realities which were *beyond* the physical properties of things, being in this sense *μεταταφυσικα* (after or beyond physics), 'metaphysics' came in the course of time to mean that department of philosophy which deals with those features of things that are hyperphysical, supra-sensible, immaterial.

In a general way we may define *metaphysics* as the *science of the ultimate principles and properties of real beings*.

Instead of investigating a particular *kind* of being, as the other sciences do, metaphysics inquires into *being as such*, whether material or immaterial, actual or possible, real or mental, and seeks to discover its most general principles and properties. It leaves out of consideration all attributes which are characteristics of physical bodies in so far as they are physical, for instance, light, heat, electricity, color, and

sound, and focuses its attention on the most general features of their reality.

The outline just given indicates the scope of metaphysics. It includes the world, the soul, God, being in general. There is a further distinction between *General Metaphysics* and *Special Metaphysics*. Cosmology treats of the material world at large; psychology, of the soul; theodicy, of God: these are the three departments of Special Metaphysics. Ontology treats of being in general; it is the department of General Metaphysics.

ONTOLOGY

Ontology (Gr., *ον*, being, and *λογος*, treatise, discourse) is the *science of being in its most general aspects*. It is called a *science*, because it contains a definite body of proved truths, arranged in systematic order. It is the 'science of *being*.' 'Being' is here taken as the opposite of 'nothing,' and it means anything that really is or can be. The idea of 'being' will be analyzed in its various meanings and connections in the following chapters. In the special sciences 'being' in some form or other is also the material object with which they occupy themselves; but they always treat of some particular kind of being, e.g., physics, of the material qualities and forces of objects, chemistry, of the constitutive elements of bodies, biology, of vital functions, and so on. Ontology does not treat of any kind of being in particular; in as much, however, as it treats of 'being,' it agrees with them in its *material* object.

Ontology is the 'science of being in *its most general aspects*.' Here we have the *formal* object of ontology. Being, as actually found in nature, must, of course, be either material or immaterial. Ontology, however, does not consider 'being' from either standpoint; it views it in those most general conditions and aspects which are common to both and are, therefore, attributes or determinations of 'being in general': these are the proper subject matter for ontology as a special philosophic science.

Consider, for example, ideas like 'relation,' 'cause,' 'quality,' 'essence,' 'existence,' 'change,' 'substance,' 'accident,' 'one,' 'whole,' and others. They have so broad a meaning and so wide an application, that they will be found in every sort of being, whether material or immaterial. They transcend the merely physical properties of things, like heat, color, and three-dimensional extension, so that they must be considered as metaphysical and ontological attributes of 'being in general.' And that places them among the proper subject matter of ontology. This being the case, it must be evident that ontology is not a mere summation of the findings of the physical sciences, but is a science in its own right, with a formal object peculiar to itself, irrespective of whether it comes to the final conclusion that the above-mentioned ideas have a valid signification or not. At any rate, the philosopher has the right and the duty to examine the validity of such ideas.

IMPORTANCE OF METAPHYSICS AND ONTOLOGY

A goodly amount of abuse and contempt has been heaped upon metaphysics and ontology by some classes of scientists and philosophers. For them the empirical sciences alone have value as knowledge. They point with justifiable pride to the marvelous results obtained by the exact methods of experimentation as used in science and the vast broadening of human knowledge achieved thereby. In consequence of this, they consider any other knowledge as superfluous, if not impossible of attainment; the knowledge of physical causes and laws alone is truly certain and valid.¹

This attitude, however, is based on a misconception. There should be no hostility of scientists against metaphysics, because metaphysics is the very basis of true science. Without ontology the fundamental ideas of science cannot be resolved into their ultimate elements, nor can their validity be established. Do not the ideas of 'cause,' 'effect,' 'quality,' 'truth,' 'relation,' and similar ones previously noted, lie at the very root of all scientific knowledge? Science simply *presupposes* the validity of these ideas; consequently, to rob them of their objective value is to rob science of the ground upon which it stands. And to accept these ideas without examination and proof means to leave the *ultimate* foundation of all knowledge open to question and doubt. Man's mind can never be satisfied with this. If this ultimate foundation is insecure, everything based on it is insecure. It is the purpose of metaphysics and ontology to *prove* this foundation valid. Thereby ontology proves the *rationality of science* in general. Instead of being hostile, then, scientists should welcome such an investigation.

As a matter of fact, scientists themselves cannot avoid metaphysical problems, nor do they actually leave them aside in their scientific discussions. Soon or later they must reach a stage in their researches where metaphysical questions are asked. The deeper they delve into the mysteries of nature the more frequently they come face to face with metaphysical problems which demand a definite solution. The scientist cannot go very far without asking himself: What is quality? quantity? causality? change? energy? What is the ultimate constitution of bodies? of protons? of electrons? of matter? What is the essential difference between truth and error, substance and accident, power and act? These are metaphysical questions, and scientists do actually discuss them. But they usually lack the philosophic knowledge offered them by a thorough understanding of ontology, and as a result they often exhibit an ignorance of fundamental ideas and principles which is harmful to the best interests of science itself. Their very attitude shows that ontology is a science of prime importance for every department of human knowledge.

METHOD AND DIVISION OF ONTOLOGY

If the charge were true that the method employed in metaphysical inquiries is totally divorced from experience and observation, then indeed there were just cause for complaint.

The inductive method of the natural sciences has proved its value beyond the possibility of doubt. The progress made by these special sciences in advancing and broadening

man's knowledge of the world gives ample testimony of its worth. A vast body of valuable truths has been discovered and systematized in the course of the last century or two, which must form the essential material for the philosopher in conducting his own researches into those wider problems cast up by metaphysics. He must accept the demonstrated findings of these physical sciences and from them draw the conclusions implied therein concerning the ultimate realities which lie behind the phenomena and laws of nature. To ignore them would indeed be fatal to the very purpose of philosophy.

The metaphysician, therefore, accepts the *facts* proposed by science, if they are unquestionably proved; he also uses the *inductive method* as his implement of investigation. Having traversed the field of these special sciences, using the scientists themselves as his guide, he then attempts to explore the unknown regions of reality which extend beyond the frontiers of the experimental sciences and effect a still greater unification of knowledge by means of a fuller grasp of those general concepts and principles which knit all things together. Having established these general concepts and principles inductively, the metaphysician then deduces other concepts, principles, and truths which flow from the former as necessary conclusions. Thus, truth and knowledge are increased through the *deductive method*. Metaphysics, therefore, uses both induction and deduction as its method. This is done especially in ontology, the science of being in its most general aspects. Thereby a great service will also be rendered to the experimental sciences in return, because

ontology will show the essential truth and validity of the fundamental ideas upon which the sciences are based and without which they seek in vain for a final verification of their conclusions. Ontology and science must assist, not oppose, each other. Their interests are mutually related and dependent. The position of ontology in the scheme of human knowledge having thus been stated and clarified, we must now divide the subject matter in such a manner as to insure the best arrangement of the problems involved. This will be done by going from the more simple to the more complex, from the more known to the more obscure. Correspondingly, ontology is divided into three major parts: (1) *Being* and its *primary determinations*; (2) the *transcendental attributes* of being; (3) the *supreme categories* of being. The subject is avowedly difficult, but its understanding is well worth the mental effort expended.

SUMMARY OF CHAPTER I

Man's mind seeks to discover the reality manifested by the phenomena of nature.

1. *Science* is the knowledge of things in their causes. The empirical sciences look for the proximate causes, while *philosophy* is the science of the ultimate causes, reasons, and principles of things, acquired by the aid of human reason alone. All sciences contain common elements and are, therefore, interrelated.

2. *Metaphysics* is the science of the ultimate principles and properties of real beings. *General Metaphysics*, or ontology, treats of 'being in general.' *Special Metaphysics* consists of three departments: cosmology treats of the material world; psychology, of the soul; theodicy, of God.

3. *Ontology* is the *science of being in its most general aspects*. It investigates realities like 'being,' 'cause,' 'effect,' 'relation,' 'quality,' 'essence,' 'existence,' 'change,' 'substance,' 'accident,' etc.

4. The *importance* of metaphysics and ontology can be seen from the fact that the realities just mentioned are fundamental to all the natural sciences. Ontology proves their validity and thereby furnishes the ultimate verification of the sciences.

5. The *method* employed in ontology is the method of induction and deduction. The *division* of ontology is as follows:

Being and its primary determinations; the transcendental attributes of being; the supreme categories

of being.

Chapter 2

THE CONCEPT OF BEING

THE FIRST THING NECESSARY IN ANY SCIENCE IS TO HAVE A clear understanding of the subject under discussion. In ontology it is 'being.' The form 'being' is the participle of the verb 'to be,' and the verb 'to be' means 'to exist,' 'to have existence.' But while the participial form of 'being' means 'having existence,' the term 'being' is usually taken as a noun, and in this substantive form it is equivalent to 'that which exists,' 'that which has existence.' This nominal definition is taken from the etymology of the term and is sufficient as a preliminary designation. There is, however, much more to the meaning of 'being' than this meager content, and it will be our first task to develop the concept of 'being' in its various phases. We have a *direct* and a *reflex* concept of 'being,' and both demand our attention.

THE DIRECT CONCEPT OF BEING

We derive the concept of 'being' from the things around us: they all are 'beings.' A tree is a being; and so is a house, a bird, a dog, a cloud, a lake, a star, a book. All objects, persons, places, facts, qualities, actions, events, are beings

or things. Whatever is present in the universe or outside of it in some way or other is a being. Each one is a particular *kind* of being, distinguished from every other by its own degrees of being. But they all have this one feature *in common* that they *exist*, and that is why we can apply to them the same word —‘being.’ The mind thus ignores all that in which things differ among themselves and centers its attention on that in which they agree, namely, the common element of ‘existence.’ ‘Being’ includes even more than the actually existing things: it embraces also all those things which do not at present actually exist, but which *can exist*, which have ‘possible existence.’ Thus we would say that the generation of men to be born a hundred years hence are possible ‘beings.’

The term ‘being,’ then, includes anything that has a *positive reference to existence*, whether this existence be actual or merely possible. The common element in actual and possible beings is their *capacity for existence*. Hence, ‘being’ in general means something capable of existing, *existible*; something capable of being actualized, *actualizable*; something capable of being realized, *realizable*.

Anything that can be positively thought of partakes of this character of ‘existibility’ — the actual and the possible, the real and the ideal, the necessary and the contingent, the material and the immaterial, the physical and the mental, the finite and the infinite. All fall under the comprehension of ‘being’; not in so far as they differ, but in so far as they agree in the one feature of something that is ‘existible.’ This meaning of ‘being’ in the sense of ‘existible’

is the meaning with which ontology occupies itself. 'Being,' then, in this widest, most indeterminate sense, is the special subject matter of ontology.

How does the mind arrive at such an indeterminate concept like 'being'? By *abstraction or precision*. Both mean the same thing, namely, the concentration of the mind's attention upon some particular phase of a thing, thereby ignoring and mentally excluding other phases or characteristics actually combined with it. A practical example will illustrate this mental process.

Take 'man.' There are many individual men, and no two are perfectly alike in every respect. Some are children, others adults; some are white, others are brown or black or yellow or copper-colored; some are male, others female; some are healthy, others diseased; some are stout, others slender; some are tall, others short; some are vivacious, others phlegmatic; and so forth. Notwithstanding these many individuating differences, all agree in this that they possess a human 'nature' — they are 'men'; and a man is a 'rational animal.' Now, the mind can ignore all these *individuating notes* or characteristics and concentrate its attention on that portion of man's being which he has in *common* with every other human being and which constitutes his *essence* as a 'man.' The essence of a thing is its 'whatness' — that which makes it to be 'what' it is and without which it would cease to be 'what' it is; everything else could be changed or missing, and the thing would still remain a member of that particular class of beings. Thus, the essence of man consists in this that he is a 'rational animal.' As long, and only as long, as he is a 'rational

animal' is he truly a 'man.' Size, age, sex, color, weight, shape, health, temperament, and similar individualizing traits, may remain, change, or disappear, but that will not affect his essential nature as a 'rational animal.'

Precision, or *abstraction*, therefore, is a process in which the mind fixes its attention upon one or other characteristic of a thing or upon an item common to many things, excluding others which are joined to it in the real order.

Precision may be either subjective (formal) or objective (material), and the difference depends upon the difference in the relation of the abstracted ideas to each other. It will be a *subjective precision*, when the ideas drawn out by the abstractive process are only *subjectively different*, i.e., when these ideas are such that they include each other implicitly, though they do not expressly mention each other. And it will be an *objective precision*, when the ideas drawn out by the abstractive process are *objectively different*, i.e., when these ideas have a different comprehension or thought-content, so that the one does not necessarily include the other. An example will make this clearer.

Man's essence, as we have seen, consists in this that he is a 'rational animal.' This involves a number of constituent elements. Man in his essence is 'rational.' As an 'animal' he is also 'sentient' and 'living.' He is also a 'body' and a 'substance' and a 'being.' We have thus resolved the essence of man into a 'rational, sentient, living, corporeal, substantial being.' Do these ideas mutually include each other, so that they are only subjectively different (subjective precision); or can we define the one without necessarily

including the other, so that they are objectively different (objective precision)? Let us see.

The idea 'sentient' means something that is capable of sense-perception; and that does not involve the idea 'rational,' because the brutes (e.g., dogs, lions, eagles, etc.) are sentient, but they are not in any sense 'rational' like man. The idea 'living' means an organism capable of immanent action (vital function); and that does not involve the idea 'sentient,' because plants are living, but they have no sense-perception. The idea 'body' means something that consists of extended matter; and that does not involve the idea 'living,' because inanimate things (metals, etc.) are corporeal, but they are not living. The idea 'substance' means something that exists in itself; and that does not involve the idea 'body,' because God is a substance, but He is not corporeal. These ideas, therefore, do not include each other, even though in man they are found together. They are objectively different, and the abstractive process, whereby they are abstracted from man's essence, is an *objective precision*.

But when we compare these ideas with the idea of 'being,' we perceive an entirely different relation. They all contain within themselves *implicitly* the idea of 'being,' because they evidently are 'beings'; and 'being' *implicitly* contains every one of these ideas, because 'being' involves every sort of reality. The only difference between 'being' and these other ideas is that they do *not expressly mention* each other, although they are and must be implicitly included in each other. The ideas 'rational,' 'sentient,' 'living,' 'corporeal,' and 'substance,' are objectively

different among themselves and have a thought. content which is not mutually inclusive; but the idea 'being' includes them all and is included in them all, so that they are only *subjectively* different from 'being' and 'being' from them.

No matter with what other idea we compare the idea of 'being' (except with 'nothing'), they are mutually inclusive: everything is a 'being' and 'being' is everything. Consequently, we arrive at the idea of 'being' by means of a *subjective, or formal, precision*.

THE REFLEX CONCEPT OF BEING

So far we have considered 'being' simply in its direct and immediate meaning, and we have examined the mode of abstraction by means of which we acquire its idea. We must now consider 'being' *reflexly*, i.e., as applied to the various kinds of things, and examine its relation to them. This will reveal a number of interesting facts.

The idea of 'being' is *first in the logical order*. By this is meant that it is the first and most fundamental in the order of ideas. Every idea contains the idea of 'being' in some form. An idea must have a content, must be the idea of something; and 'something' is always a 'being.' All knowledge is of things. The content of an idea will thus always represent a modification or a certain kind of 'being.' Hence, it is the most basic idea, the one into which all other ideas are ultimately resolved, the one without which nothing can ever be known.

The idea of 'being' is *first in the chronological order*. This statement cannot, of course, be demonstrated in any

strict fashion. No one can prove its truth from personal experience, because no one will be able to recall the first idea that he had in time. Nor can it be proved through observation of other minds. Obviously, children would be the only ones who could tell us, and they are incapable of telling us when they obtain their first idea and what its content is. The above statement is made in consequence of a general fact universally observed, namely, that man always passes in his knowledge from the more confused and indeterminate ideas to those more clear and more detailed. Since, however, the most confused and indeterminate idea is that of 'being' or 'thing,' and since this idea is involved in every concept, it is natural to suppose that the child's process of knowledge will have started with the simplest notion of 'thing' ('being') and gone from there to the more detailed modes and kinds of 'being.'

The idea of 'being' is the *narrowest in comprehension* and the *widest in extension*. By the comprehension of an idea we understand the sum total of all the attributes or thought—elements which constitute the idea; it is expressed in the definition of the content of the idea. By the extension of an idea we understand the sum total of all the individuals and groups to which an idea can be applied.¹ The comprehension of 'being' is the simplest of all, since it contains but a *single* element, namely, that which is 'existible,' that which is not 'nothing.' Its extension is the widest of all ideas, because it can be applied to absolutely *everything* that exists or can exist —finite and infinite, God and creature, material and immaterial, substance and accident.

Since the idea of 'being' is composed of but a single element, the 'existible,' it is the *most empty* of all ideas. It ignores every kind and special modification of entity in its comprehension and expresses solely the one element common to all things, namely, their capacity for existence. But while 'being' is the most empty of all ideas, the most indeterminate of all concepts, it has a *positive content of reality*. Hence, it cannot be identified with 'nothing,' as it is done by *Georg Hegel* (1770—1831), the German idealist philosopher. He does this because of the indeterminateness of the idea of 'being.' But indeterminateness does not deprive 'being' of all positive content. If it did, and if 'being' were equivalent to 'nothing,' then there would be no difference between 'being' and 'non-being,' between 'thing' and 'no-thing.' That would be a patent contradiction in terms, a logical and ontological monstrosity. After all, 'being' must always be 'being' and not its opposite. An examination of 'nothing' will show this more plainly.

BEING AND NOTHING

'*Nothing*' is the *absence of being*. It presupposes the knowledge of 'being' to begin with. It is only by having a previous concept of 'being' and then denying its presence that we acquire the idea of 'nothing.'

We can even distinguish between different *kinds* of 'nothing,' depending on the different kinds of 'being' which are considered to be absent. Thus, we speak of absolute and relative 'nothing.'

An *absolute nothing* is the *total* absence of being in every conceivable form. It is, obviously, only a mental abstraction. Being actually exists and has always existed, at least so far as God is concerned. There could never have been a time when there was an absolute nothing; because in that case no being could ever have come into existence.

A *relative nothing* is the absence of a definite *kind* of being. This relative nothing will again be either negative or privative. A *negative nothing* is the *mere absence* of some kind of being in a thing: the absence of wings or fins or claws or hoofs in a man; the absence of life or sight or hearing or speech in a stone; the absence of locomotion or feeling or memory in a plant. A *privative nothing* is the absence of some kind of being in a thing that is *fit* to have it and normally *ought* to have it. Cases in point are: the absence of wings in a sparrow, of fins in a perch, of hoofs in a horse; the absence of life in a dog, of hearing in a squirrel, of speech in man; the absence of locomotion in a giraffe, of memory in a lion. In these instances the absence of the perfection mentioned is a real *privation*, since these beings lack something that they ought to have according to their normal constitution.

From the above it is evident that Hegel's contention, that 'indeterminate being' is identical with 'absolute nothing,' is erroneous. If the two ideas were identical in content, then whatever is excluded from the idea of 'absolute nothing' would also be excluded from the idea of 'indeterminate being.' But this is not so. *All* being, of whatever type and kind, is excluded from 'absolute nothing'; but only a definite or *determinate kind* of being is excluded from the idea of

‘indeterminate being.’ The two ideas are thus seen to be objectively and essentially different. Certainly, both ‘absolute nothing’ and ‘indeterminate being’ exclude every determinate kind of being; but ‘absolute nothing’ is absolutely devoid of *all content* in its idea, while ‘indeterminate being’ still retains the *positive content* of ‘being in general.’ The mere fact that both agree in one point does not make them identical and equivalent; just as little as the fact that the ideas of ‘plant’ and ‘animal’ exclude the idea of ‘rationality’ will make the plant and the animal to be the same reality and identical thing. ‘Indeterminate being’ is still always ‘being,’ while ‘absolute nothing’ is never ‘being’ under any and all conditions.

DEFINITION OF BEING

‘Being’ admits of *no strict philosophic definition*. Such a definition would demand a proximate genus and a specific difference. The proximate ‘genus’ includes within its comprehension all the essential elements of the genera above it and therefore includes all the beings that are cognate or similar in nature to the thing which is to be defined. The ‘specific difference,’ on the other hand, brings in the distinctive element which separates this thing from all others of a similar nature, by showing in what manner it is different from all others with which it might be erroneously identified.

Take as example ‘man.’ Man is defined as a ‘rational animal’; ‘animal’ is his proximate genus, ‘rational’ is his specific difference. The proximate genus ‘animal’ includes

within its comprehension all the essential elements of the genera above it, because an 'animal' is a 'sentient, living, corporeal substance'; and this shows all the beings which are in some way similar to man-brutes, plants, inanimate bodies, substances. The specific difference 'rational' is the one distinctive essential element which distinguishes 'man' from every other 'animal'; it thereby makes him a species of his own and separates him from every other 'animal' and also from every other genus or species, including plants and inanimate bodies.²

It will be noted that the generic idea must always be *wider in extension* than the idea to be defined; and the idea expressed by the specific difference must always be something not already contained in, but *extraneous* to, the generic idea. A definition, therefore, if it is to be a real and strict one, must be made up of two objectively different ideas — one wider and one narrower than the thing to be defined, so that the combination of both gives the exact designation of the thing. This, however, can never be the case in a definition of 'being.' 'Being' is the supreme idea, the widest and simplest and most indeterminate which the mind possesses; *there can be no wider idea than 'being.'* Consequently, the mind can find no idea which could, in any strict sense of the term, serve as a true genus for 'being.' The most we can attempt, then, is a *descriptive definition*, and even that will not elucidate the idea, since none of the ideas which could be employed will be clearer and simpler than 'being' itself. As was pointed out above, 'being' is the first idea in the logical order, and no other idea is

intelligible without a previous understanding of the idea of 'being.

Viewed positively, 'being' can be described as that *which exists or can exist*, the 'existible'; viewed negatively, it is *whatever is not nothing*. That is the best we can do in describing it.

SUMMARY OF CHAPTER II

The term 'being' is derived from the verb 'to be' and means something that has, or can have, existence.

1. *The Direct Concept of Being.* We form the general idea of 'being' by contemplating the things around us; they are things, 'beings.' All things have a common element — actual or possible existence; they are *existible*.

The mind arrives at the indeterminate idea of 'being' by means of a subjective (formal), not an objective (material), *abstraction or precision*.

2. *Reflex Concept of Being.* The idea of 'being' is the first in the logical and chronological order. It is the narrowest in comprehension and the widest in extension; it is the most empty of all ideas. But the idea of 'being' always has a positive content of reality and as such is not identical with 'nothing.'

3. *Being and Nothing.* 'Nothing' is the absence of being. *Absolute* nothing is the total absence of being, while relative nothing is the absence of a definite kind of being. A *relative* nothing is negative, when it is the mere absence of some kind of being in a thing; and it is *privative*, when it is the absence of some kind of being in a thing that is fit for it and ought to have it. 'Absolute nothing' is the absence of all being, while 'indeterminate being' is merely the absence of a determinate kind of being.

4. *Definition of Being.* A strict philosophic definition is impossible, because there is no idea wider than 'being' that could serve as its genus; a descriptive definition is the best

than can be given, and even this will not elucidate the idea of 'being,' because no idea is more intelligible than this. Viewed positively, 'being' is that *which exists or can exist*; viewed negatively, it is *whatever is not nothing*.

Chapter 3

KINDS OF BEING

THE IDEA OF 'BEING' IS THE SIMPLEST, WIDEST, AND MOST indeterminate of all ideas. 'Being' is anything and everything that does or can exist; whatever is not nothing is a 'being.' Such is our concept of it in its most general form. Naturally, 'being' itself can never exist in such indeterminateness; it appears always as some determinate *kind* of being, as something which possesses definite *degrees* of reality, as individual things or *entities*. Every single thing in nature is a 'being,' and we could make a classification of 'being' according to the ordinary types of things which are found in the universe. Such a classification, however, belongs more properly to the special sciences. Ontology considers only those kinds of 'being' which run across the lines of all the sciences, as characteristic of 'being in general.' A classification from this standpoint is the division into *real* being, *ideal* being, and *logical* being.

REAL BEING

A *real being* is anything that has, or can have, *existence independent of man's actual knowing*. By this is meant that it must be able to exist even when not thought of by man, That nothing can exist without the knowledge of God, is true; but it must be existible without dependence on man's knowledge-act. There are a number of subdivisions of real being which are important in this connection, and their general concept will be given.

ACTUAL AND POSSIBLE BEING. THE 'ACTUAL' BEING IS ONE THAT *really exists* at the present moment. We all are aware of ourselves as existing realities, we are conscious of our existence we are, therefore, actual beings. The same is true of every article in my room; of the house I live in; of the trees, garden, hills, sky, clouds, sun, etc., which exist in the universe at large, even if we do not know that they exist. They may be visible or invisible, physical or psychical, corporeal or spiritual: so long as they have existence here and now, they are actual.

The 'possible' (potential) being is one that does not actually exist, but is *capable of existence*. Such a being is not present in any way in the existing order of things; but it is such that it is not intrinsically impossible and can receive existence, provided there is a cause that can give it existence. For instance, in the spring, when the seed is placed into the soil, the future crop is not actually present; but it is a possible or potential reality, in as much as the seed has the inherent power (Lat., *potentia*, power) to bring

it forth so that it can exist (Lat., *pot-ens, potis esse*, to be able to exist).

SUBSTANTIAL AND ACCIDENTAL BEING. A 'SUBSTANCE' IS A BEING that *exists in itself* and does not need another to exist in as in a subject of inherence. Such are the ordinary objects we observe in the physical world — a table, a box, a book; metals and non-metals; plants, animals, men; the rivers and lakes, the hills and plains, the sun and the moon and the stars. These things exist in themselves and have a being of their own.

An 'accident' is a being that cannot exist in itself, but *needs another to exist* in as in a subject of inherence. Such beings are too weak in entity to exist without a subject; they require a substance to support them in their being and existence. Accidents are modifications of substances. Such are color, quantity, quality, action, motion, etc. Motion, for instance, never exists for itself and in itself; it is always a body that moves from place to place. Action cannot exist except in a body that acts. Color is always found in a body that is colored.

NECESSARY AND CONTINGENT BEING. A BEING IS SAID TO BE necessary, when its *non-existence is impossible*. It may be either absolutely or conditionally necessary.

A being is 'absolutely' necessary, when its non-existence is impossible under any and all conditions. In such a being existence is a constituent of its very essence. Such a being

simply *must exist*. An absolutely necessary being can never have been produced, because production implies that there was a moment when it did not exist and then received existence through this production; an absolutely necessary being, however, can never have been non-existent even for a moment. Consequently, such a being cannot be a produced being, but owes its existence to its own infinitely perfect essence (*ens a se*). God is conceived as such a being; His existence is identical with His essence, and as such His essence can never be without actual existence.

A being is 'conditionally' or 'hypothetically' necessary, when its non-existence is impossible under a certain given condition. Thus, no man's existence is necessary; however, given his existence, he must exist as a 'rational' being, because 'rationality' is one of the elements which constitute his existing essence. Again, a plant need not exist; but if it exists, it must have 'life.' So, too, a stone need not fall; but if it falls, it must of necessity have a certain amount of speed in its motion.

A 'contingent' being is one whose *non-existence is possible*. Actual existence, therefore, is not an essential element of its nature. It would involve no contradiction to conceive of such a being as non-existent. Essentially, such a being is indifferent to existence or non-existence. If it actually exists, it could not have received its existence in virtue of its own essence, but must have received it from some other being which produced it. This is obvious. Since its existence is not due to itself, it must be due to another being; this means that it is produced by this other. If it were not produced by another, it would owe its existence to its

own essence, and then it would not be contingent but necessary.

FINITE AND INFINITE BEING. THESE ARE TERMS WHICH ARE frequently used, and their exact meaning should be well understood.

A 'finite' being is one whose reality is *limited in perfection*. All things composing this physical world are finite. Not one has being, power, or existence which can truly be conceived as not limited in some manner. They are limited in size, in energy, in time, in space, in quality, in action, in endurance. As long as there is the slightest limitation of any kind in a being, it cannot strictly be accounted as anything but finite.

An 'infinite' being (Lat., *finis*, limit; *infinitem*, without limit, limitless) is one which has *no limit in its entity or perfection*. Our idea of the 'infinite' is negative in form, since it denies a limit; but it is positive in content, because it asserts the supreme fullness of entity and perfection. A being may be actually or potentially infinite.

A being is 'actually' infinite, when it has *reality without limit*. If this being is unlimited in one definite *kind* of reality only, while limited in other ways, it is said to be 'relatively' infinite. In mathematics, for instance, we speak of an infinite line; we mean thereby that it is limitless in length, but a line is limited in width and depth to such an extent that it is conceived as being without these two dimensions. But if a being were without any limit in the positive fullness of *all perfection*, including every kind and degree without

measure, it would be 'absolutely' infinite. A being of this nature must possess the perfections of all other beings and essences within itself, but stripped of their imperfections and limitations; and since a spiritual substance is more perfect than a corporeal substance, the absolutely infinite being must be a spirit whose essence is purest actuality without any admixture of potentiality. It is thus that we conceive God to be.

Something is 'potentially' infinite, when it is always actually finite in the amount of its reality, but is *limitless in its potentiality for receiving more reality*. Its possibility of receiving more reality will never reach an ultimate limit, for the reason that the store of possible reality which it did not yet receive is inexhaustible. A potentially infinite being, therefore, is always actually finite in perfection, and it can never become actually infinite in perfection.

ABSOLUTE AND RELATIVE BEING. THAT IS 'ABSOLUTE' WHICH CAN be thought of or can exist *without reference to another*. It is self-sufficient, independent; it does not need another. If it can exist without reference to another, it is *ontologically* absolute. Only the necessary being, God, is absolute in this sense. If it can be 'thought of' without reference to another, it is *logically absolute*. Ordinary objects are logically absolute, because we can form an idea of them without reference to another object; such are the idea of 'dog,' 'clock,' 'star,' 'gold,' 'eagle,' 'man,' etc. Their meaning is clear, and they can be defined by themselves.

That is 'relative' which can exist or be thought of only in *reference to another*. If the existence is relative, the thing is said to be *ontologically* relative. The existence of all creatures is of this kind, because they owe it to God. If the very concept of a thing, as expressed in its definition, involves reference to another, it is *logically* relative. We see this logical relation in ideas like 'father,' 'child,' 'brother,' 'king,' 'president,' 'front,' 'rear,' 'north,' 'east.'

Some of these divisions are the subject of considerable controversy, like 'substance' and 'infinite' and 'absolute.' It is not our purpose here to pass judgment on the validity of such concepts. They, and the problems connected with them, will be treated at greater length in different departments of philosophy. For the moment we are concerned merely with stating these classifications and nominal definitions, because they are commonly used, and their signification should be clearly understood, so as to avoid confusion of thought.

IDEAL BEING

By *ideal being* we understand any object in so far *as it is known*. It is also called *intentional* being. The mind of man in the act of knowledge is not like a mirror in which the known object is simply reflected, or like a photographic plate upon which the object makes an impression, so that the mind is purely passive in the process. The mind itself is actively engaged in this process and contributes its share to the production of the cognitional image of the object. No object leaves its position in external space and passes with

its bodily presence into the sense in sense-perception and into the intellect in thought. Nor does the mind pass out of the human person and envelop the physical object. Nevertheless, there must be a union between mind and object in some fashion in the act of knowledge, otherwise the mind could not be aware of its presence and existence. In the act of knowledge, then, there must be a *substitute presence* or image of the object *in the mind*. This *presence to awareness*, this sense-presence or thought-presence, is what we mean by 'ideal being.' An object as 'known,' therefore, obtains a mental or ideal existence whereby it manifests its presence to the perceiving mind; and this 'ideal existence' is entirely different from its real or physical existence which it has as an object in its own right, within the realm of the physical universe.

That the mind is not purely passive in the process of knowledge, can be seen in the fact that the mind can err in its knowledge. If the object were the only active agent in this process, it would always reveal itself as it is, and the mind could never obtain an erroneous impression of it, and thus a false judgment about it would be utterly impossible and unintelligible. The only reason why we can make a mistake about an object is, that the mind itself actively produces an intentional or ideal image of the object, and this image may not always correspond perfectly with the object in its physical being. In epistemology it was shown¹ that sense-knowledge of things is largely a matter of *interpretation and subjective construction*, based upon impressions received from the physical objects. Both object and mind contribute their share to the production of the

image, and the result is something different from the physical object itself. In the act of knowledge, then, the object receives a special form of being or existence, characteristic of knowledge itself, which is styled its 'ideal' or 'cognitional' or 'intentional' being.

This ideal being of a thing appears in two forms, *sensible* and *intellectual*, depending on the type of faculty which represents the object. Brutes and men have sense-perception of things, and these known things thus obtain a 'sensible intentional (ideal) being' in this form of knowledge. But men also have an intellect and form intellectual ideas, strictly so called, of these things; the cognitional existence thus obtained by the known things is an 'intellectual intentional (ideal) being.' Many philosophers of a sensist and phenomenalist frame of thought deny the difference between sense and intellect and assert that there is nothing but sense-knowledge in man. It is the duty of the psychologist to investigate this claim. The terms 'sense' and 'intellect,' however, are so current and so generally recognized as essentially different that the ontologist is entitled to accept the distinction, at least in a general way, and give a nominal definition of both. Whether these terms possess ultimate validity, will be a matter for discussion in psychology. So much is certain: man and brute are different in some way, and the difference manifests itself in man's power to think, an activity which is not definitely observed in the brutes. That alone is a sufficient reason for the classification of 'ideal being' into 'sensible' and 'intellectual.'

There is another point to bear in mind in this connection: sense-images are always concrete, individual, vague and indistinct with complexity and minuteness of detail, while idea-images are abstract, universal, sharp and distinct notwithstanding complexity and minuteness of detail.² This is a further reason to divide 'ideal being' into 'sensible' and 'intellectual,' even though there would be no essential difference between sense and intellect.

LOGICAL BEING

We speak of *logical being* in opposition to real being and ideal being. Our knowledge is naturally of things that are found in external nature, of extra-mental realities. Trees, buildings, birds, animals, earth, stars, are realities independent of our mind and its operations; the mere fact of their being known or unknown does not make them less real. They have their own being, 'real' being. An 'ideal' being, it is true, is dependent on the mind for its existence as known; but the ideal being of a thing always presupposes its real being, and hence is not purely mental.

There are, however, a variety of beings which have no existence and being whatever except as *products of thought*, creations of the mind; they have no objective existence in the world outside. The mind, in acquiring its knowledge of a thing (real being), makes concepts of them (ideal being), and this knowledge represents the thing as it exists in nature. But the mind goes a step further and analyzes these concepts, compares them, relates them, and

thus arrives at new concepts which have value only *in the order of thought*.

Such are the concepts of *genus*, *species*, and others of a similar character. 'Animal,' we say, is the 'genus' of man, and 'rational animal' is his 'species.' There is no such *thing* in nature, as a mind-independent entity, which could be called a 'genus' or a 'species'; the only beings that exist in nature are individuals. But the mind by its abstractive power conceives them as a unit and expresses them in one concept which it then applies to all the individuals as a class. As a 'genus' or a 'species' they have no existence except in the mind, in the logical order of thought. *They are logical beings, thought-beings.*

So, too, the mind in its thinking makes sentences with *subjects* and *predicates*, *nouns* and *adjectives*, *prepositions* and *adverbs*; and so on, with the other mental beings we call 'particles of speech.' We do not find such things existing in the world, as we see trees, buildings, hills, lakes, dogs, horses; they are not physical entities, but exist only in the mind.

We are now in a position to define *logical being*; it is *anything that has objective being only in the mind*. Whatever is conceived by the mind as a being, although it has not, and cannot have, any objective existence in nature precisely as thus conceived, is a thought-being, a logical being.

There are two main classes of logical being: one without a foundation in reality, and the other with a foundation in reality.

A logical being may be *without a foundation in reality*, and then it is a pure fabrication of the mind. Such would be 'a square circle,' 'a stick with only one end,' 'a corporeal spirit,' and similar contradictory concepts. Each element in such a dual concept actually denies and removes the reality given by the other, and so nothing is left that would represent a positive reality. Yet they are treated by the mind as *if* they represented some positive content and had real being. Obviously, such concepts or thought-beings can exist nowhere except in the mind.

A logical being with a *foundation in reality* is one which cannot exist in nature in the *precise manner in which it is conceived*, but there is a reason in the things of nature why the mind conceives it thus. Such a logical being will be either negative, or privative, or relative.

A *negative* logical being is a concept representing a mere absence of being; for instance, a 'vacuum,' 'sightlessness,' 'lifelessness.' Ideas of this sort have a content which is negative and *as such* is not a reality which can exist for itself outside the mind. Yet there is a foundation in reality for these concepts, because they are negations of some reality.

A *privative* logical being is a concept representing a lack of being. Examples would be 'death,' 'blindness,' 'paralysis,' 'neuralgia,' and similar concepts. If we compare such logical beings with negative logical beings, we will immediately see the difference. 'Sightlessness' signifies the mere absence of sight, while 'blindness' is the privation of sight in one who ought to have it. 'Lifelessness' is the absence of life in a being which is not supposed to possess

it, for instance in a stone; but 'death' is the privation of life in a being which formerly was living.

A *relative* logical being is a concept representing some relation between thoughts, sentences, inferences, and any part of them, considered as a being. The relations existing between subjects and predicates, between the premises and conclusion in an argumentation, between parts of speech, between genera and species, etc., are logical entities. So, too, are the mental laws which govern them, for instance, the laws of the syllogism, of induction, of education, of predication.

Such things have a foundation in reality. The negative and privative logical beings have their foundation in the physical world, in as much as the objects found therein are limited and imperfect and are affected by negations and privations in some part of their being.

These, then, are the different kinds of being: real, ideal, and logical. They all belong to the extension of 'being in general' and give us a better understanding of what 'being' really is: it includes everything mental and extra-mental, everything in the order of existing or existible things. Our next task will be to investigate how 'being' is found in these different kinds of being. And this brings us to the contraction of being in general to its inferiors.

SUMMARY OF CHAPTER III

There are three main kinds of being: real, ideal, and logical.

1. *Real* being is anything that has, or can have, *existence independent of man's actual knowing*. It includes: actual and possible being; substance and accident; necessary and contingent being; finite and infinite being; absolute and relative being.

2. *Ideal* being is any object in so far *as it is known*. It is also called 'intentional' or 'cognitional' being. It consists in the presence to awareness which an object has in the mind when known. The mind is not purely passive in knowledge, but is actively engaged in the process and contributes its share to the production of the cognitional image. The ideal being is either sensible or intellectual.

3. *Logical* being is anything that has objective being *only in the mind*. There are two kinds: with or without a foundation in reality. Logical beings, which have a foundation in reality, are either negative, or privative, or relative.

Chapter 4

THE CONTRACTION OF BEING

THE VARIOUS KINDS OF BEING HAVE BEEN NOTED. THEY ARE widely diverse in nature and character. Since they all belong to the extension of 'being in general,' the vague concept of indeterminate 'being' must be narrowed down or contracted in its extension to these different classes. The *contraction of being* is the reduction or narrowing of the extension of 'being' to its inferiors by means of the addition of some element to the comprehension of 'being,' thereby including some definite beings and excluding others from this extension.

CONTRACTION BY LOGICAL COMPOSITION

'Being' is contracted to its inferiors, not by means of a physical or metaphysical composition, but by means of a *logical composition*.

By composition we mean the union of elements that are distinct from each other. If these elements are such that they are objectively different in idea and physically different as things, then their union is effected through a *physical* composition. If they are objectively different in idea, but

really identical in their physical being as things, their union is effected through a *metaphysical* composition. And if these elements are neither objectively different in idea nor physically different as things, but merely different in the sense that the one idea contains implicitly and vaguely what the other expresses explicitly and determinately, their union is effected through a *logical* composition. The contraction of 'being' to its inferiors is made by means of a logical composition.

When we melt copper and zinc together, or when hydrogen and oxygen unite to form water, we have a physical composition. Here these realities are not only different in idea, but also as things. When the elements 'living body' and 'sentiency' are united together to form an 'animal,' we have a metaphysical composition. These elements are objectively different in idea, but in the animal as an existing reality they are not physically different as things; the very body of an animal which is 'living' is at the same time also 'sentient,' and 'sentiency' in the animal is an expression of its 'life.' When, however, we contract the idea 'being' to its inferiors 'substance' and 'accident,' we have only a *logical* composition, because these realities are neither altogether objectively different in idea nor physically different as things. This will be clearer from the following considerations.

When we discussed the mode of precision employed in abstracting the idea of 'being' from the essence of 'man,' we showed that the ideas of 'rational' and 'animal' are objectively different, because they are not mutually inclusive. The wider idea of 'animal' is contracted or

narrowed down to its inferior 'many by *adding* the idea 'rational' to the idea 'animal'; and the idea 'rational' is truly *foreign* and *extraneous* to the idea 'animal.' This, then, represents a metaphysical composition.

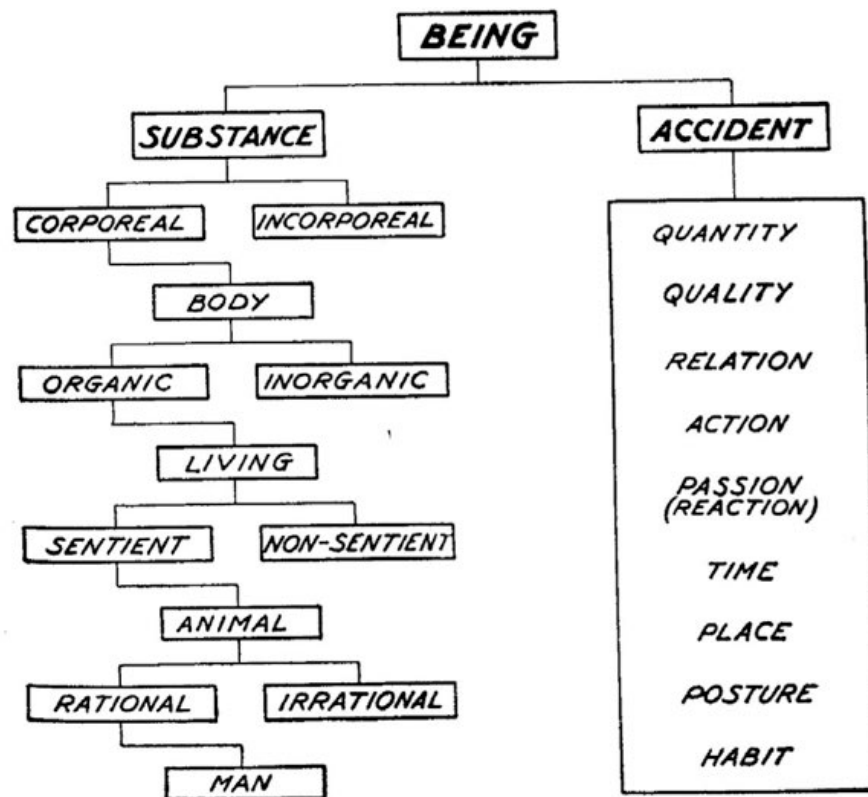

When we contract the idea of 'being' to its inferior ideas, like 'substance,' 'accident,' 'body,' 'animal,' 'man,' or to any other idea, does this also involve a metaphysical composition, such as exists between 'animal' and 'rational' in man? It does not. If it did, the element or idea *added* to 'being' would have to be objectively different from it and *positively excluded* from its content; it would have to be an element foreign and extraneous to 'being,' something not already contained in it. Now, what element could be added to 'being' which is not a 'being' in some form or other? The only element or idea that is *outside* the idea of 'being' is the idea of 'nothing'; but it must be evident that 'being' can make no composition with 'nothing,' because the latter can *add nothing positive* to the idea of 'being.'

Comparing, then, the idea of 'being' with that of 'substance' and 'accident' or any other idea, we find that the latter can add to 'being' nothing which would be objectively different from 'being,' nothing which would be new and extraneous to it. Whatever they contain of positive reality is merely an explicit and determinate *form of being* and is already contained in the idea of 'being in generals in an implicit and indeterminate manner. They are, therefore, neither physically different as things, nor objectively different in idea, from 'being' itself. And that is precisely the characteristic mark of a logical composition. Hence, the contraction of 'being' to its inferior members is effected, not

through a physical or metaphysical, but through a *logical composition*.

BEING IS NOT A TRUE GENUS

Nothing seems plainer than that 'being' should be the genus of 'substance' and 'accident,' because they form the natural divisions of 'being.' This can be seen from the following diagram:

'Substance' and 'accident' certainly appear to be well-defined species under the genus of 'being.' But this is only apparently so. The reason why 'being' cannot be considered a true genus follows with necessity from what has just been

said about the logical composition involved in the contraction of 'being' to its inferiors. A *species* is the result of the union between a *genus* and a *specific difference*; and the specific difference is an element new and extraneous to the content of the genus, something not contained in the genus in any way as a part of its comprehension. Unless, then, the content of the specific difference is something *new* and *extraneous* to the comprehension of the so-called genus, the latter is not a true genus. And that is the case with 'being' as applied to 'substance' and 'accident.'

The reason is obvious. One cannot find any specific difference *outside* the idea of 'being' which could make a *true difference* and thus constitute a true species, because any such difference would always be a 'being' in some form and on that account would already *be contained* in the idea of 'being.' 'Substance' is a being 'existing in itself,' and 'accident' is a being 'existing in another.' But 'existence,' whether 'in itself' or 'in other,' is already a modal form of 'being'; consequently, it is contained within the comprehension of 'being' in general and is nothing truly new and extraneous to 'being.' The only idea outside the comprehension of 'being' is the idea of 'nothing'; and that, of course, can never become a mark to distinguish one species from another. A specific difference *must be a positive element* of distinction between two species, so that the one is realized *with it* and the other *without it*; that is precisely what constitutes the difference between one species and another. 'Being,' then, is not a true genus for 'substance' and 'accident,' because we can find no specific difference outside its comprehension.

Since 'being' is no strict genus and since it includes every possible thing in the scale of reality, it is properly called *transcendental*, i.e., something which transcends or surpasses all classes or categories of determinate beings.

BEING IS AN ANALOGOUS IDEA

Three terms, depending upon their perfect or imperfect signification, can be considered in this connection: univocal, equivocal, and analogous. A *univocal* term is one which designates a number of things in an *identical sense*. Such things are of the same kind, so that the word used to name them has the same meaning throughout. The term 'dog,' as applied to mastiffs, bulldogs, terriers, poodles, etc., is a univocal term. The term 'metal,' used to designate gold, silver, copper, tin, etc., is also univocal. This is true of most terms signifying objects belonging to a certain class. An *equivocal term* is one which is used of diverse things, so that it has *entirely different meanings*. For instance, 'pen' as an instrument for writing and as an enclosure for animals; 'coach' as a vehicle and as an athletic director; 'page' as a leaf of a book and as an attendant at court. Here the identical word has entirely different meanings, as will be seen at a glance; it is, from this standpoint, the opposite of a univocal term.

An analogous term stands midway between these two: it is one which applies to *unlike things, partly for the same and partly for a different reason*, so that it is used in a meaning that is partly the same and partly different. There is always some fundamental relation present in such things,

entitling the mind to designate them by the same term; hence, such a term is not equivocal. On the other hand, because of their partial unlikeness, the term is not used in a strictly identical sense, and so it is not univocal. That is why it is called analogous. Take the term 'healthy.' Man is termed 'healthy'; and since health is a condition affecting a living body, the term is applied here in an absolute sense. But we also say that a medicine is 'healthy,' because it causes health; a complexion is 'healthy,' because it is an indication of health; food is 'healthy,' because it preserves health; exercise is 'healthy,' because it promotes health: here the term is used in a relative sense, because the word 'healthy' can only be applied to them in relation to the health of a living body with which they have some connection. The meaning is not strictly identical nor is it entirely different; the things so designated are really unlike, but the fundamental relation to 'health' unites them in the same term and concept.

The term 'being,' as applied to its inferiors, e.g., to the infinite and the finite, to substance and accident, to the absolute and relative, etc., is manifestly *not equivocal*. It certainly does not apply to them like the term 'pen' to an instrument of writing and to an enclosure for animals. The objects designated here by the term 'pen' are totally different in meaning and have no common bond between them. But the infinite and the finite, the absolute and the relative, substance and accident, are 'beings' in the true meaning of the term; they contain a common element and are related by a common bond, namely by their mutual reference to existence, because all are 'existibles.'

The question now arises: Does not this common element 'existible' imply the selfsame meaning in these inferiors of 'being,' so that the term 'being' is applied to them in a *univocal* manner? At first glance one would think so. But an exact analysis of the conditions involved in univocal predication will show that 'being' is not applied to them in a strictly identical sense.

In order that a term be univocal in its application to its inferiors, two things are required: first, that there be *one thought-content* or comprehension corresponding to the one term, and this thought-content must really be *present in the inferiors*; second, that this one thought-content be present in all of them in a *strictly uniform manner*.

The first condition is undoubtedly verified in the application of 'being' to the infinite and the finite, to substance and accident, to the absolute and the relative, etc. 'Being,' in the sense of 'existible,' is truly found in them all. They exist; or at least they can exist. There is no intrinsic contradiction in any of these concepts as such, and that is sufficient to consider them at least as *possible beings*. They are, then, beings in the sense of something 'existible'; and in this sense the thought-content of 'being' is really found in them in a true manner.

But the second condition is not fully verified. When a thought-content is realized in a number of things in a *strictly uniform manner*, they are, so far as this element is concerned, *perfectly alike* and do not differ in this particular respect. If they differ nevertheless, this difference is due to some other element *added* to it and this element is added to it *from without* as something new and

extraneous. For instance, 'animal' is a univocal term applied to man and brute. In so far as man and brute are 'animals,' i.e., 'sentient,' they do not differ among themselves. The distinguishing element 'rational,' the point in which they differ, is *not contained* in the concept of 'animal' at all and is added from without. This, however, is not true of 'being' as realized in its inferiors. 'Being,' of course, is found in every one of these concepts; but the element in which the 'infinite' differs from the 'finite' and 'substance' differs from 'accident,' etc., is not anything outside the concept of 'being' and added extrinsically to it, *but is itself also a being.* Hence, 'being' is not only that in which they agree; it is also that in which they *differ* and as such, then, it is not found in them in a strictly uniform manner. Thus, the 'infinite' is a being that is of itself eternal, immutable, absolutely independent; the 'finite' is created, changeable, temporal, dependent on the infinite. 'Substance' is a being that exists in itself and does not need another to inhere in; 'accident' is something that cannot naturally exist in itself, but must always depend on its substantial support for existence. These are essentially different modes of 'being,' and thus 'being' is *not realized* in them in a *strictly uniform manner*. In consequence of this the term 'being' does not apply to them in an entirely identical meaning. And since a term, which applies to its inferiors in a manner and meaning partly the same and partly different, is called analogous, 'being' is an *analogous term*.

If we inspect the fundamental relation which forms the basis of the analogy here, we find that it is an *analogy of intrinsic attribution*. For this two conditions are demanded:

the element common to the things designated by the same term must be present in them in a true and genuine sense, and not merely applied to them as a figure of speech; this element must be found in the one member in an independent and absolute sense, and in the other member relatively and with dependence on the first. Such is the nature of 'being' as applied to the infinite and the finite, to substance and accident, to the absolute and the relative. In all these the concept of 'being,' their common element, is present in a true and genuine sense, and not merely as a figure of speech; they are truly and genuinely *beings*, because they really are existible. But it is equally clear that the *infinite* (God) is 'being' in an absolute and independent manner, while the *finite* (creature) can have 'being' only in relation to, and with dependence on, the infinite (God). So, too, it is the *substance* which has 'being' primarily, while *accidents* can exist only in and with the substance. Similarly, the absolute is of its very nature something which is independent in its 'being,' while the *relative*, as its name indicates, is dependent on the absolute. We thus see that these dual members, although they are true beings, are such that 'being' is realized in them in a totally different manner, the second member having a relation of dependence on the first: the first can exist without the second, but the second cannot exist without the first. And this relation of dependence forms the basis for the analogy of *intrinsic attribution* between them, since that is what is meant by analogy of 'intrinsic attribution.'

Summing up, we find that 'being' is contracted to its inferiors, not by means of a physical or metaphysical

composition, but by means of a *logical composition*. 'Being' *is not a true genus*, but an *analogous idea*, based on an analogy of intrinsic attribution. These distinctions may not seem very important, but they play a vital part in the controversy between theism and pantheism. If 'being' were a true genus, embracing as members God and the world, there would be danger of merging both in the higher reality of 'being in general'; and that would be pantheism. A confusion of this sort would indeed be disastrous in many ways. A clear-cut knowledge of 'being' will avoid this intellectual pitfall without much difficulty.

SUMMARY OF CHAPTER IV

By the *contraction of being* we understand the reduction or narrowing of its extension to its inferiors by the addition of some element to its comprehension or thought-content.

1. '*Being*' is contracted to its inferiors, not by means of a physical or metaphysical composition, but by means of a *logical composition*. By a logical composition is meant the union of elements which are neither objectively different in idea nor physically different as things, but merely different in the sense that the one idea contains implicitly and vaguely what the other expresses explicitly and determinately. If we contract the idea 'being' to 'substance' and 'accident,' we find that whatever reality the latter contain is merely an explicit and determinate *form of being* and is already included in the idea of 'being in general' in an implicit and indeterminate manner. They are, therefore, neither objectively different in idea, nor physically different as things, from 'being' itself.

2. *Being is not a true genus*. 'Substance' and 'accident' are not true species under 'being' as their genus. A 'species' is the result of the union between a 'genus' and a 'specific difference'; and the specific difference is an element *new* and *extraneous* to the content of the genus. In order, then, that 'being' be a true genus, we must find a specific difference which would be extraneous to the concept of 'being' and be added to it in the Species. But every such difference would itself be a 'being' of Some kind, and then it would not be extraneous to 'being.'

The only thing outside 'being' is 'nothing,' and 'nothing' can make no difference between things.

3. *Being is an analogous idea.* A 'univocal' term is one that is applied to a number of things in an identical sense. An 'equivocal' term is one that is applied to a number of things in entirely different meanings. An 'analogous' term is one which applies to unlike things, partly for the same and partly for a different reason, so that it is used in a meaning partly the same and partly different.

The term 'being,' as applied to the infinite and the finite, to substance and accident, to the absolute and relative, is not equivocal, because these things are real beings. But neither is it applied to them univocally, because the thought-content of 'being' is not found in them in a *strictly uniform manner*. It is found in the infinite, in the substance, and in the absolute in a primary and independent sense, while it is found in the finite, in the accident, and in the relative in a secondary and dependent sense. 'Being' is thus an analogous term, based on an analogy of *intrinsic attribution*.

Chapter 5

THE SUPREME PRINCIPLES

SO FAR WE HAVE INVESTIGATED 'BEING' WITH REGARD TO ITS content, in order to have a clear idea of its meaning. Our idea of 'being' has been amplified by the enumeration of the main classes in which it can be realized; we have become acquainted in a general manner with real being, ideal being, and logical being. The concept of 'nothing' has also been examined, thereby setting off the positive content of 'being' against the negative content of 'nothing.' We have also seen how the idea of 'being' is contracted to its inferiors, to the infinite and the finite, to substance and accident, to the absolute and the relative. We must now turn our attention to the supreme principles of being.

THE NATURE OF A PRINCIPLE

A *principle*, generally speaking, is *that from which something else proceeds in any way whatever*. In order that something be a real principle, it is necessary: first, that the principle be *prior* to the reality which proceeds from it; secondly, that this priority be grounded in the things

themselves on account of some *special connection*. This priority may be one of time, or of nature, or of origin.

A *priority of time* exists when the principle has an existence which precedes that of the reality which flows from it. Fire is prior in time to the boiling of the water which it causes; an inventor is prior in time to the machine he makes; an electric current is prior in time to the movement of the motor which it operates; the sun is prior in time to the light it emits. A *Priority in nature* exists when the principle possesses a nature

Whose presence is necessary for the existence of something which proceeds from it, even though this nature be not prior in time. Thus, substances must be prior in nature to their own accidents. because the latter presuppose a substance as the subject in which they have their being. The substance of a body is prior in nature to the three-dimensional quantity which modifies the body; a rose is prior in nature to the color found in it; a man is prior in nature to the vital functions which exist in his being. These accidents are present at the same time as the substance, but they could not exist unless the nature of the substance were presupposed, because they proceed from it as from their natural principle. A *priority of origin* exists when the principle is neither prior in time nor in nature, but prior in origin, to the reality which proceeds from it. We have an example in the Blessed Trinity, as held in Christian theology. The Father is the principle of origin for the Son and is prior to Him in this sense, but this origin involves neither a priority of time nor of nature. Obviously, it is

beyond the scope and possibility of philosophy either to prove or disprove this last type of priority.

The *special connection* between the principle and that which proceeds from it may belong either to the logical or to the ontological order. It will be a *logical* connection, when the truth of one statement depends upon the truth of another, from which it flows; this latter statement would then be a logical principle. For instance, the premises in an argumentation are the logical principle for the conclusion. It will be an *ontological* connection, when the entity of one thing depends on the entity of another; such a principle would be an entitative or ontological or metaphysical principle. The connection existing between effects and causes is ontological; thus, hydrogen and oxygen are the ontological principle of water, because water depends in its being on the entitative union of hydrogen and oxygen. While logical principles also interest the ontologist, his main concern is with ontological or metaphysical principles; and among these the supreme principles of being demand his particular attention. By the *supreme principles of being* are understood those highest principles which are *immediately derived from the concept of 'being'*: the Principle of Identity, the Principle of Contradiction, the Principle of Excluded Middle, and the Principle of Sufficient Reason.

THE PRINCIPLE OF IDENTITY

The *Principle of identity* rests immediately on the concept of 'being.' A 'being' is something 'that is.' It is evident, then, that 'a being is a being.' And since 'nothing' is that 'which is

not,' it is also evident that 'a not-being is a not-being.' Here we simply compare 'being' with itself and 'not-being' with itself, and the truth of the judgments is intuitively clear to the mind without the need of any demonstration; the relation of self-identity expressed therein is objectively self-evident. The Principle of Identity is the natural formulation of this relation. It is formulated in different ways: *Whatever is, is; and whatever is not, is not: Everything is what it is: Everything is its own being: Being is being, and not-being is not-being.*

This principle may seem to be a mere tautology, as if it were stated that 'A man is a man' or 'A stone is a stone.' But the identity enunciated in the principle has a wider application than this. It applies with equal force and truth to the statements that 'A man is a living substance' and 'A stone is material.' Here, too, the mind affirms an identity *in this case* between 'man' and 'living substance' and between 'stone' and 'material'; and these are obviously not tautological statements. The Principle of Identity is thus exemplified in every affirmative judgment made by the mind and is valid in both the logical and ontological orders.

THE PRINCIPLE OF CONTRADICTION

This principle is based on a comparison of 'being' with 'not-being.' In comparing these two concepts, it is transparently clear to the mind that the one is not, and cannot be, the other. They mutually exclude each other with an absolute necessity. 'Being' is simply 'being' and cannot be 'not-being,' otherwise 'being' would be 'nothing' and would not

be 'being' at all. The same is true of 'nothing': it is 'not-being' and as such can never be 'being,' otherwise 'nothing' would not be 'nothing' but would be 'being.' In other words, something 'that is' can never, under any and all conditions, be something 'that is not.' And since these two concepts can never be united in the mind as identical, but must be universally and necessarily in opposition to each other as contradictories, this self-evident truth is expressed in the Principle of Contradiction: *It is impossible for a thing to be and not be at the same time: A thing cannot be and not be something at the same time.*

It must be borne in mind, however, that the phrase 'at the same time' has more than a temporal meaning. It means as much as: from the same standpoint, at the same time, in the same circumstances, under the same conditions, in the same respect. The statement could be true that 'It is possible for rain to fall and not to fall at the same time,' if we refer to different localities; but it could not be true about the selfsame rain in the selfsame locality. It is also true that 'A boy can be a man,' if we mean that he can be a man at a later period of his life; but a boy cannot be a man while he is still a boy. The principle, therefore, applies to things taken *in the same respect*; and then it will be obvious that they cannot both 'be' and 'not be' something at the same time.

The principle has *universal application*. It applies with equal validity to things temporal and eternal, to things finite and infinite. Thus, it is impossible for a man to walk and not to walk, to think and not to think, to live and not to live, to be a millionaire and not to be a millionaire, to own a car and

not to own a car. It is impossible to be immortal and yet mortal, to be uncreated and yet produced, to have all perfection and yet lack entity, to be omniscient and yet be ignorant of something, to be omnipotent and yet be incapable of producing some possible being. From this it must be clear that the identification of 'being' and 'nothing' on the part of *Hegel* is sheer absurdity. Consider this statement of his: "The distinction between Being and Nought is, in the first place, only implicit, and not yet actually made: they only ought to be distinguished. A distinction, of course, implies two things, and that one of them possesses an attribute which is not found in the other. Being, however, is an absolute absence of attributes, and so is Nought. Hence, the distinction between the two is only meant to be; it is quite a nominal distinction, which is at the same time no distinction. In all other cases of difference there is some common point which comprehends both things. Suppose, e.g., we speak of two different species: the genus forms a common ground for both. But in the case of mere Being and Nothing, distinction is without a bottom to stand upon: hence, there can be no distinction, both determinations being the same bottomlessness . . . Nothing, if it is thus immediate and equal to itself, is also conversely the same as Being is . . . In Being we have Nothing, and in Nothing Being.... In Becoming the Being which is one with Nothing, and the Nothing which is one with Being, are only vanishing factors; they are and they are not."¹ This may be good idealistic monism, but it is an absolute violation of the Principle of Contradiction and the destruction of the foundations of all knowledge, science, and philosophy.

THE PRINCIPLE OF EXCLUDED MIDDLE

This principle is also the result of a comparison between 'being' and 'not-being.' It is called the *Principle of Excluded Middle*, because the mind intuitively perceives that between 'being' and 'not-being' there is no middle or third thing which would be left, if both 'being' and 'not-being' were removed. Such a middle thing either 'is' or 'is not.' If it 'is,' then it is a 'being'; if it 'is not,' then it is a 'not-being.' Consequently, it will be either a 'being' or a 'not-being,' but not a middle thing *between* the two which is neither the one nor the other. If it is the one, it is not the other; and if it is not the one, it must be the other. It certainly cannot be both 'being' and 'not-being' at the same time, because that would be impossible in virtue of the Principle of Contradiction. This principle has also been formulated in a number of ways: *A thing either is or is not: Everything must either be or not be: Between 'being' and 'not-being' there is no middle or third thing possible.*

As in the case of the two foregoing principles, this principle rests immediately on the relation between 'being' and 'not-being.' It needs no demonstration to prove its truth, because a mere understanding of the concepts of 'being' and 'not-being' and of their relations to each other is sufficient to make it evident. If it is impossible for a thing to 'be' and 'not to be' at the same time, then such a thing must either 'be' or 'not be'; nothing could be simpler or truer. The Principle of Excluded Middle is thus seen to flow naturally and logically out of the Principle of Contradiction. If the latter is valid, the former must be valid also.

Like the foregoing principles, this principle applies *to all things* without exception, if it is a question of contradictory distinctions. No matter what point may be mentioned, it is always 'either — or.' God is either infinite or not infinite, either eternal or not eternal, either created or not created, either a person or not a person. This stone is either quartz or not quartz, either heavy or not heavy, either small or not small. This man is either white or not white, either an American or not an American, either old or not old, either sick or not sick. There can be no middle ground between these contradictories: a thing cannot be both, and it must be either the one or the other of the two.

THE PRINCIPLE OF SUFFICIENT REASON

Everything, in so far as it is a 'being,' has reality. Whatever reality a being has, it must have it either of and by itself or from and by another being; in the first case it has the *sufficient reason* for its reality in itself, and in the second case it has it in the other. This is so obvious that the mere statement suffices to show its truth. And if it has no reality, it is no being at all, and this is simply due to the fact that it has not received reality either of itself or from another being; in both cases it is a 'not-being' because it has *no sufficient reason* for its reality. If it could have reality nevertheless, it would have to receive it from 'nothing.' But 'nothing' has no reality itself and can, therefore, never give reality to anything. Consequently, were such a reality without a sufficient reason, it would both 'be' and 'not be' at the same time: it would 'be,' because that is the

supposition; and it would also 'not be,' because, having no sufficient reason to account for its reality except 'nothing,' it could receive only that which 'nothing' could give, which is precisely nothing. But 'to be' and 'not to be' at the same time is a violation of the Principle of Contradiction; and that is an absurdity. Hence, if a being has reality, it must have it either of itself or from another, i.e., it must have a sufficient reason for itself: *Nothing is without a sufficient reason: Everything must have a sufficient reason for its being and existence.*

METAPHYSICAL AND LOGICAL PRINCIPLES

These metaphysical or ontological principles are called *First Principles*, because they follow immediately from the first and fundamental concept of 'being.' They are primarily metaphysical principles of *reality*. They have, however, also a *logical* character, and as such are the first and fundamental principles or *laws of thought*. This must be so. Ideas are mental representations of reality, of things. In order truly to represent things, they must conform to the reality they represent. Because things are what they are and are not what is different from themselves, we can judge and think that they are so. Reality is thus the standard and norm according to which the mind must regulate and formulate its judgments concerning reality. Just as reality itself must conform to the metaphysical laws of being, so all judgments must conform to these same laws. Consequently, the laws of being must also be the laws of thought; in other

words, these supreme metaphysical laws are at the same time the supreme logical laws.

It must be possible, then, to translate these metaphysical laws of being into logical laws of thought. This is not a difficult task.

The Principle of Identity will read:

Whatever is true of a thing must be affirmed of it:

Truth is always truth, and falsity always falsity.

The Principle of Contradiction will be:

Something cannot be both true and false at the same time: Contradictories cannot be true at the same time.

The Principle of Excluded Middle can be

expressed: Contradictory judgments must be either true or false.

The Principle of Sufficient Reason can be stated as follows:

There must be a sufficient reason for the truth or falsity of a judgment.

To say that these are the supreme metaphysical and logical principles, does not mean that all being and all truth are included in them in such a way that all particular beings and all particular truths derive their *origin* from them. Were this the case, it would be possible to deduce the existence of single beings and single truths from them; then

a knowledge of these principles would enable the mind to acquire a knowledge of all being and all truth in their various determinate forms by means of a gradual unfolding and detailed *development* of these principles. But this cannot be done. These principles are based on the concept of 'being in general,' and the latter is the emptiest and most indeterminate of all ideas. 'Being in general' is a mental abstraction; as such, it *exists* nowhere as a *reality* which would possess in the richness and fullness of its existing entity all other existing beings and truths. As an *idea* 'being in general' includes all beings and all truths in its extension, but not as an existing reality. The supreme principles of being and thought, therefore, are *not productive* principles or *causes*, but *regulative norms* and laws to which the particular beings and truths must conform. Particular beings and particular truths derive their origin from *sources outside* these principles. That the sun exists, is not due to these principles. But *if* and when it exists, then it must conform to these laws. If the sun exists, it is a sun, according to the Principle of Identity; it cannot be a sun and not a sun at the same time, according to the Principle of Contradiction; it must either be or not be a sun, according to the Principle of Excluded Middle; and it must have a sufficient reason for its reality and existence, according to the Principle of Sufficient Reason. And from a logical standpoint, it must be true that it is a sun; it cannot be true and false at the same time that it is a sun; it must be either true or false that it is a sun; and since the judgment about the sun agrees with its reality, there is a sufficient reason for the truth of this judgment. These principles themselves,

however, *do not confer reality and existence* on the sun; nor do they enable us to know of the existence of the sun. And what has been said here about the sun, pertains to every other kind of being; whether it be the earth, a tree, a dog, a house, a desk, an apple, a man, or God. They do not owe their being to the First Principles; but, if they have being, their being and the truths concerning their being are regulated according to the laws inherent in these metaphysical and logical principles. Such, then, is the nature of these supreme metaphysical and logical principles.

THE MOST FUNDAMENTAL PRINCIPLE

The question has been raised among philosophers as to which of these supreme metaphysical and logical principles is the *most fundamental*.

That the Principles of Excluded Middle and of Sufficient Reason cannot be the most fundamental, should be clear from the foregoing exposition of these principles. They are without doubt a development of the Principle of Contradiction. It is only because a thing 'cannot be and not be something under the same respect,' that it follows with necessity that a thing must 'either be or not be' and that it 'must have a sufficient reason.' Their validity is thus clearly based on the Principle of Contradiction; they rest solidly on the validity of the latter as upon their primary principle.

It is not so easy to decide whether the Principle of Identity or the Principle of Contradiction is the most fundamental in the ontological and logical order. *Aristotle*

and his followers, the scholastics, have always considered the Principle of Contradiction to be the more fundamental of the two. Their view of the matter held the ascendancy and remained practically unchallenged. In more recent times, *Gottfried W. Leibnitz* (1646—1716) advocated the opinion that the Principle of Identity was the first and foremost. In his first essay on Locke he expressed himself as follows: “My view is that nothing shall be taken as first principles but experiences and the axiom of identity or (what is the same thing) contradiction, which is primitive.”² Later on, however, in his *New Essays*, he came out more definitely in favor of the priority of the Principle of Identity: “In the natural order the statement, that a thing is what it is, is prior to the statement that it is not another.”³ At first, this latter view of Leibnitz might seem to be the more logical. But on closer inspection, if we consider these principles from the standpoint of the certitude of human knowledge, we must say that the *Principle of Contradiction* is the most fundamental. As *D. Card. Mercier* states the situation: “That of Identity is first, i.e., the first in the order of the mind’s analysis, or genetically first; but in the regressive order, when it is a question of the firm foundation of the certitude of our knowledge, the Principle of Contradiction is the last, the touchstone of all certitude.”⁴

The reason is this. If we accept the Principle of Identity as a mere tautology, then, it is true, it is prior to the Principle of Contradiction; but a tautology is no principle of being or thought. When, however, we wish to assert with strict certitude and necessity that ‘whatever is, is,’ we really

intend to affirm that ‘whatever is, is *necessarily so*’ and cannot be otherwise. But this is tantamount to saying that a thing cannot be and not be something at the same time: and that is the *Principle of Contradiction*. When we, therefore, consider the practical import of the Principle of Identity, we find that it really coincides with the Principle of Contradiction. Taken for itself, the Principle of Identity is, according to *Tilman Pesch*, “vague and indeterminate, so that it is rather the root and the imperfect germ of principles”⁵ than a full-fledged principle itself. Consequently, the Principle of Contradiction is the most fundamental among the supreme principles of being and of thought.

We may even go a step farther and say that the Principle of Contradiction is the most fundamental *of all principles* of being and thought. The most basic idea involved in every thought and thought-process, in every substantial and accidental reality, is the idea of ‘being.’ This idea of ‘being’ is thus the first in the *logical* and *ontological* order. Hence, the principle immediately expressive of this idea in thought and reality must be the most basic and fundamental principle in the same order. But it is the Principle of Contradiction which does this, because it is constituted solely by the idea of ‘being’ as compared with its directly opposite idea of ‘not-being.’ This principle, therefore, is implicitly contained in every other principle and gives to them whatever they possess of certitude and stability; they stand and fall with the Principle of Contradiction.

With this we conclude our investigation into the concept of ‘being in general’ and the supreme principles which flow

from it. These principles are the ultimate laws of all being and all thought. We must now direct our attention to an examination of *the primary determinations of being*.

SUMMARY OF CHAPTER V

1. *The Nature of a Principle.* A principle is that from which something else proceeds in any way whatever. There must be priority of the principle relative to the reality which proceeds from it; and this priority may be one of 'time,' or of 'nature,' or of 'origin.' This priority must be grounded in the things themselves on account of some *special connection*; this connection will be 'logical,' when the truth of one statement depends upon the truth of another, or 'ontological,' when the entity of one thing depends on the entity of another.

2. *The supreme principles* of being are those highest principles which are immediately derived from the concept of 'being.' These are:

- *The Principle of Identity:* Whatever is, is; and whatever is not, is not: Everything is what it is: Everything is its own being: Being is being, and not-being is not-being.
- *The Principle of Contradiction:* It is impossible for a thing to be and not to be at the same time: A thing cannot be and not be something at the same time.
- *The Principle of Excluded Middle:* A thing either is or is not: Everything must either be or not be: Between 'being' and 'not-being' there is no middle or third thing possible.

- *The Principle of Sufficient Reason*: Nothing exists without a sufficient reason: Everything must have a sufficient reason for its being and existence.

3. *Metaphysical and Logical Principles.* The metaphysical or ontological principles just mentioned are also logical principles, i.e., they are laws of thought as well as laws of being. Reality is the standard according to which we must regulate and formulate our ideas and judgments; consequently, the metaphysical laws are at the same time logical laws. These principles, however, are not the productive principles or causes of things, but the regulative norms or laws to which the particular beings and truths must conform.

4. *The Most Fundamental Principle.* The Principles of Excluded Middle and Sufficient Reason are a development of the Principle of Contradiction; they are, therefore, not the most fundamental. The Principle of Identity really means that 'whatever is, *is necessarily so*' and cannot be otherwise; and that is equivalent to the Principle of Contradiction. Consequently, the latter is the most fundamental of the supreme principles of being and of thought.

The Principle of Contradiction is also the most fundamental *of all principles*, because it is constituted solely by the idea of 'being,' and the idea of 'being' is the most basic idea involved in everything in the logical and ontological order.

Chapter 6

ACT AND POTENCY

SO FAR 'BEING' HAS BEEN CONSIDERED IN ITS MOST GENERAL features. Certain kinds of being have been enumerated, but this was done more for the purpose of obtaining a better understanding of the concept of 'being' itself. 'Being in general,' as was noted, is characterized by extreme indeterminateness, signifying anything that is not nothing, anything that is existible. *Real* being, of course, is not as indeterminate as all this; it has a distinct and definite character of some sort. And it is this distinct and definite character of real being which we mean when we speak of the 'determinations' of being.

Among the manifold determinations of 'being,' we are mainly interested in those *primary determinations* which are *transcendental*; namely those which constitute the most fundamental distinctions of 'being in general' and go beyond all the ordinary classifications of beings as found among actual things. Such are the basic divisions of 'being' into act and potency, essence and existence, the necessary and contingent, the infinite and the finite.

CONCEPT OF ACT AND POTENCY

Strictly speaking, these terms cannot be defined. Act and potency are immediate divisions of 'being.' In order to be defined, 'being' would have to be their proximate genus in the definition; but 'being,' as was pointed out before, is not a strict and true genus. This must be borne in mind in the following explanations and discussions.

According to philosophical terminology an *act* (Lat., *actus*) means any entity of whatever kind and nature which perfects and determines a thing in its being. Thus, the term 'act' includes the *power* or faculty as well as the *operations* of that power, because this power is a perfection for the thing which has it; it includes every *accidental* modification of a being, because every accident (e.g., color, heat, weight, shape, etc.) perfects the being in some way; it includes every *essential* entity, because nothing is more perfecting for a thing than its essence; it also includes *existence*, because existence is a perfection for a being. Whatever a being *has* or *is* in a positive manner is an 'act' for it. Man's substantiality, materiality, life, sentiency, and rationality, are 'acts'; his quantity, size, shape, age, sex, color, health, are 'acts'; his powers of reason and of will, of locomotion, of digestion, of seeing, hearing, feeling, etc., all these are so many 'acts,' perfecting and determining his being in its respective order as 'man.' And so with all other beings. The term 'act,' therefore, has a specialized and technical meaning, much wider than its signification in ordinary language.

Potency (Lat., *potentia*, power) is the *capacity or aptitude for something*. It is the correlative term to 'act.' 'Potency' is always the capacity or aptitude in reference to something which a being is not or has not, but which it can be or can receive. Any being, in so far as it has not as yet received a certain 'act' or perfection, but is capable of receiving it, is said to be 'in potency' for this act. Hydrogen, for example, has the 'act' of hydrogen; and oxygen has the 'act' of oxygen: but both have the 'potency' of water; they are 'actually' hydrogen and oxygen, but 'potentially' water. Water, on the other hand, is 'actually' water; but it is 'potentially' hydrogen and oxygen, because it has the aptitude to be resolved into them. Common salt is 'actually' salt, but it is 'potentially' chlorine and sodium.

If we consider the *relation between 'act' and 'potency'*, we find that it is the relation of the completing to the incomplete, the determining to the determinable, the perfecting to the perfectible. Since these are relative terms, it is obvious that an entity may be a determination and perfection for a being in one way and thus be an act, and it may also be determinable and perfectible in itself and thus be a potency. The intellect, for example, is a positive perfection of the mind, and thus an 'act,' for man; but the intellect itself is perfected by the actual thinking process (which is an 'act' for the intellect), and it is, from this point of view, a 'potency.' Similarly, the power of locomotion is a perfection, an 'act,' for a resting dog; but the act of running is a perfection for this power of locomotion, and the power of locomotion is thus seen to be a 'potency' with regard to this act of running. An entity, therefore, can be both an 'act'

and a 'potency,' when considered from different viewpoints; but never with reference to the same perfection under the same respect, because that would violate the Principle of Contradiction.

KINDS OF ACT

There are as many kinds of 'acts' as there are kinds of 'being,' because every being as such is a *perfection*. We must, then, make a division along general lines.

Essence, Existence, Property, Accident. The act or actuality of the essence is the act which perfects and determines a thing in its species. It is that constitutive element or principle in a thing which makes it to be just this particular kind of thing and no other. It is the 'act of essence' which makes a horse to be a horse and not a cat, a rose to be a rose and not a cucumber, a man to be a man and not an elephant, silver to be silver and not copper.

The act of *existence* is the act perfecting and determining a thing in such a manner that it is no longer a merely possible being, but is present in the real order. A hundred years ago we were merely possible beings; now we have the 'act of existence.'

The act of *property* is the act of perfecting and determining an essence in such a manner that the entity it gives to the being *flows necessarily from its nature, without being strictly essential*. The essence of man, for instance, consists in being a 'rational animal'; never, not even for a single moment, can he cease to be such without destroying his human nature. The power of speech, of using tools, of

laughing, are not part of this essence, but they flow necessarily from his being as a rational animal. These powers demand a body, because speech and laughter and the use of tools are bodily operations; they also demand rationality, because only a thinking mind can express itself by means of speech, laughter, and the use of tools. Hence, only a 'rational animal' is capable of these operations. Since, however, they are only the results of his essence, rather than part of the essence itself, they are 'properties' of man and as such are an 'act of property' for him.

The act of *accident* is the act perfecting and determining a being in such a manner that the entity it gives *does not flow necessarily from the essence of the being*. Red hair, white skin, one's weight, height, shape, etc., are all 'accidental acts' of the body. Thoughts, emotions, states of consciousness, etc., are 'accidental acts' of the mind. All operations proceeding from powers or faculties belong to this class, whether they be animate or inanimate, such as motion, light, heat, electricity, gravitational attraction, and so on.¹

Primary and Secondary Act. A primary act is one that is the *first in a series of acts*, so that it has another act proceeding or capable of proceeding from it. Thus, the nature or essence of a being is an 'act,' and so are its faculties and the operations of these faculties. There exists a natural hierarchy among them, because the operations proceed from the faculties, and the faculties proceed from the essence or nature; hence, since this essence or nature is the ultimate principle from which both faculties and operations proceed, it is a 'primary act' in reference to

them. For the same reason the faculties or powers of a being are a 'primary act,' when compared to the operations which they perform. Man's rational nature, for instance, is the 'primary act' with reference to his intellect and thoughts; and, in a more limited way, the intellect is the 'primary act' with reference to the thoughts.

A secondary act is one that *presupposes another act in a definite series*, so that it proceeds from a primary act. Every action and operation is a 'secondary act' with regard to the power or faculty from which it flows. Thought is a 'secondary act' flowing from the intellect as a 'primary act.' A boy who has the ability to whistle is, in so far, in possession of a 'primary act' or faculty; but when he practices his art and warbles a tune, he has the 'secondary act' of whistling.

Pure and Mixed Act. A pure act is one *without the least admixture of potentiality*. It is all actuality (act), all perfection, complete determination. Such a being can have no capabilities or aptitudes. There is nothing in such a being which could be considered determinable, perfectible: it is completely and absolutely determined, actualized, perfect. It lacks no entity nor can it receive an increase of entity, for the simple reason that it possesses all possible actuality. Of course, the Infinite Being alone is such a 'Pure Act.'

A mixed or non-pure act is one that in some form or other *has an admixture of potentiality*. Such a being does not possess its actuality always and all at once; its perfection is acquired gradually and successively, and it is subject to development and change. Whatever has faculties

is such a 'mixed act,' because they are not always in operation. All creatural beings, inanimate as well as animate, belong to this class, because they are limited in essence and acquire and lose many determinations in the course of their existence.

KINDS OF POTENCY

Potency, or potentiality, as we have seen, is the capacity or aptitude for some act. There are two main kinds of potency: objective and subjective.

Objective Potency. By *objective* potency we understand *the capacity of a non-existent being for existence*. As this descriptive definition indicates, such a being has not as yet actual existence and is a non-being; there is, however, a possibility of its being brought into existence by some cause, and so it has a 'capacity for existence.' It is, therefore, not an absolute nothing. A hen, for instance, has laid a fertilized egg. The future chick is as yet non-existent; in as much, however, as the capability is there for the chick to be hatched later on, the chick is said to be 'in objective potency.' Sodium and chlorine are present in separate containers; salt is not yet an existing reality, but it has 'objective potency,' because the necessary elements are there for the production of salt.

Subjective Potency. *Subjective* or *real* potency is *the capacity of something existing for an act*. This potentiality may be such that it consists in a special power of *receiving* an 'act' from another being, or in a special power of

communicating an 'act' to another: this gives rise to the distinction between 'receptive' and 'operative' potencies.

A *receptive* subjective potency is *the capacity for receiving act*. A child's mind has the receptive potency of acquiring knowledge from a book or a teacher. Iron has the receptive potency of being magnetized. Water has the receptive potency being heated to the boiling point or of being frozen to ice. This receptive potency will be *natural*, when it is a capacity for receiving an act in virtue of its natural powers. Such are the instances just mentioned. It will be an *obediential* receptive potency, when it is a capacity for receiving an act which transcends its natural faculties, provided this act be given to it by a superior power. Thus, a dead body cannot, in virtue of its own powers, come to life again; but it can receive life a second time, if God reanimates it: a dead body, therefore, has an 'obediential subjective potency' for renewed life.

An *operative* subjective potency is *the capacity for doing something*; it is the power of a thing to bring forth some act. Electricity is a power capable of producing mechanical motion, light, heat. Dynamite can effect violent explosive detonations. The mind can produce thoughts.

An operative subjective potency is either supernatural or natural it is *supernatural*, when it is the power to produce effects which transcend the capabilities of physical nature. Miracles, or acts involving a suspension of physical laws, can be performed only by a supernatural power. It is *natural*, when the effects produced are the result of an operative power inherent in the essence of a being and acting according to the laws of nature. That the eye sees,

the ear hears, the mind thinks, the magnet attracts, the bird flies, the motor runs — all this is the effect of natural operative subjective potencies.

A natural operative potency may be passive or active. It is *passive*, when it presupposes its object and must be stimulated to activity by it; given the stimulation, however, the passive operative power becomes actively engaged in producing its proper effect. The eye, for instance, presupposes objects and light to stimulate it; it then produces vision through its own activity. Gasoline must be ignited in a motor cylinder; then its inherent forces explode and drive the pistons. A race horse must be led to the post and urged to race; but it does its own galloping. A potency will be an *active* natural operative potency, if it produces or prepares its own object. Thus, the vegetative powers first prepare the food in the digestive tract before assimilating the food into the tissues. Plants produce their own seeds. Bees produce their own wax for building cells and produce the honey for their own food.

POSSIBILITY, OR OBJECTIVE POTENCY

Possibility, or objective potency, as has been explained above, is *the capacity or aptitude of a being for existence*. A ‘possible’ being, then, is one that has an aptitude for receiving existence. *Impossibility* is the incapacity or inaptitude of a being for existence. An ‘impossible’ being is thus a being that has no aptitude for receiving existence. Possibility and impossibility are such important concepts in

the philosophy of 'being,' that they deserve special treatment.

Many things we know to be 'possible' from the simple fact that we observe them as actually existing; if they were 'impossible,' they would not exist and we could not observe them. Trees, potatoes, vines, cows, giraffes, cats, iron, gold, buildings, automobiles, airplanes, men — all are seen to really exist and consequently are 'capable of existence.' We cannot observe 'impossible' things, because such things do not and cannot exist; but we know certain things to be impossible by way of conclusion from what we see existing and from self-evident first principles. We know what 2 and 3 mean, and in consequence of this we also know that their sum cannot possibly be 7 or 8. We understand the nature of circles and squares, and we perceive that 'square circles' are an impossibility. We have a clear perception of the essence of man as a 'rational animal,' and we are absolutely sure that a man without the power of reason cannot possibly exist.

What, then, is required and suffices, in order that a being be *adequately possible*, i.e., that it can really pass from a state of non-existence into a state of existence? Two things are essentially demanded and suffice.

The *first requirement* is that there be a *compatibility of the being's constitutive elements*. These elements must not be mutually exclusive in any way, not antagonistic, incompatible, repugnant. If one element denies and removes as much as the other posits, it is obvious that such elements mutually remove each other; the result would really amount to a non-being, and a non-being cannot exist.

Take a 'square circle.' A circle is a geometrical figure that consists entirely of a curved line; the curved line eliminates all straight lines in the thing. A square, on the other hand, consists essentially of four straight lines of equal length and joined at their ends to make one figure; the straight lines thus eliminate any curved line. Hence, a 'square circle' would be a figure of straight lines, since it is 'square' (and that removes the curved line), and it would also be at the same time a figure consisting of a curved line, since it is a 'circle' (and that removes the straight lines); the final result would be that there are neither straight nor curved lines, and so nothing would be left that is capable of existence. effect and cause: a cannon can obviously do more than a popgun.

ENTITY AND KINDS OF POSSIBLES

It may seem odd to speak of the *entity of a possible being*. From the standpoint of actual existence, the possibles are clearly nothing, since they are as such non-existent. It would be wrong, nevertheless, to identify them absolutely with 'nothing.' For one thing, the possibles are *capable* of existence; 'nothing' is absolutely incapable of existence. Then, too, the possibles have a *positive thought-content* (e.g., a 'mountain of gold,' a 'crystal palace'); 'nothing' has no content whatever and can be known only through a negation of being. Finally, the possibles differ among themselves by means of *objectively different concepts* (e.g., there is a real difference between a 'mountain of gold' and a 'crystal palace'); but between 'nothing' and 'nothing'

there is no difference. The possibles are, therefore, real, though not actual; 'nothing,' however, is neither real nor actual. The possibles thus possess a *positive metaphysical entity*, but not any kind of physical actual entity.

As for the *various kinds of possibility*, we distinguish between intrinsic and extrinsic possibility.

Intrinsic (metaphysical, absolute, logical) possibility is the capacity or aptitude of a being for existence, due to the compatibility or *non-contradiction of its constitutive elements*. There must be no contradiction in terms, no contradiction in the thought-content or comprehension of its idea. A large circle is intrinsically possible, but a square circle is not. A winged horse is intrinsically possible, but a body-less horse is not, because, being an animal, it must be a corporeal substance. A stick a million miles long is intrinsically possible, but a stick with only one end is not, because it would be finite and infinite in length. The latter alternatives all contain a contradiction in terms.

Extrinsic (relative) possibility is the capacity of a being for existence *in virtue of the power of an efficient cause capable of producing it*. Next year's automobiles are extrinsically possible, because the men and machines are in existence to make them. For the same reason houses, clothes, shoes, tools, railways, dirigibles, guns, boats, motors, books, and similar things, are extrinsically possible. But it would be extrinsically impossible for a man to lift a five-ton truck with his hands alone, to run a mile a minute, to jump fifty feet into the air, to make a tree or a bird. Extrinsic possibility always presupposes intrinsic possibility.

Extrinsic possibility may be twofold: physical and moral. *Physical* possibility is the possibility due to the powers of a thing *acting according to the laws of nature*. For instance, a heavy charge of electricity in opposite clouds is physically capable of producing a flash of lightning. A normal man possesses the physical possibility of standing without support for five minutes; it may be physically impossible for a sick man to do the same. Other instances of physical possibility and impossibility are given in the preceding paragraph.

Moral possibility is the possibility of free agents to do something *without grave difficulty*. Where a grave difficulty is present, an action is said to be 'morally impossible,' although it may still be physically possible. It would be a serious inconvenience and therefore a moral impossibility for a man with pneumonia to perform hard labor. It is morally possible for a man of perfect health to walk five miles over good roads and in good weather for the sake of signing a contract that will net him a pretty sum of money; but it would be morally impossible for a child to walk a mile to school, when the temperature is 30° below zero.

Comparing these various kinds of possibility with one another, we arrive at the following general principles or laws of possibility: Moral possibility always includes physical and metaphysical possibility; physical possibility includes metaphysical. But what is metaphysically possible need not for that reason be physically or morally possible; and what is physically possible need not be morally possible.

Metaphysical impossibility excludes physical and moral possibility; and physical impossibility excludes moral

possibility. But what is morally impossible, need not for that reason be physically impossible; and what is physically impossible need not be metaphysically impossible.

A perusal of the examples given above will show the truth of these conclusions. The greatest number of possibles is found among things that are metaphysically possible, and the smallest number among those that are morally possible. Conversely, the greatest number of impossibles can be found among those that are morally impossible, and the smallest number among those that are metaphysically impossible.

Having seen the immediate reason or ground why things are said to be possible or impossible, it is but natural to ask ourselves, What is the *ultimate ground* of the possibility of things? This question reaches down into the very root of all 'being' and deserves special attention.

SUMMARY OF CHAPTER VI

The *primary determinations* of 'being' are transcendental, i.e., they constitute the most fundamental distinctions of 'being' in general and go beyond the classifications of beings as found among the ordinary things. One such primary determination of 'being' is *act* and *potency*.

1. *Act* is *any entity perfecting and determining a thing in its respective order of being*. This includes all operations, all powers or faculties, all accidental modifications, essence, and existence, of things: whatever a being has or is.

Potency is the *capacity or aptitude for something*. The relation between act and potency is the relation of the completing to the incomplete, of the perfecting to the perfectible, of the determining to the determinable.

2. *Kinds of Act*. There are 'acts' of essence, existence, property, and accident; primary and secondary; pure and non-pure or mixed.

Kinds of Potency. We distinguish between *objective* potency, which is the capacity of a non-existent being for existence, and *subjective* potency, which is the capacity of an existing being for an act. Subjective potency may be 'receptive' or 'operative.' A receptive potency may be either 'natural' or 'obediential'; an operative potency may be either 'supernatural' or 'natural'; a natural operative potency may be either 'passive' or 'active.'

3. *Possibility, or Objective Potency*. In order that a being be *adequately* possible, it is required and suffices that there be a compatibility of its constitutive elements and that there

exist an efficient cause capable of conferring existence upon it. The compatibility or non-contradiction of these constitutive elements gives to a being *intrinsic* (metaphysical, absolute, logical) possibility; and the existence of a capable efficient cause gives to a being *extrinsic* (relative) possibility.

4. *Entity and Kinds of Possibles.* Though the possibles do not exist, they are not absolutely identical with 'nothing': possibles can exist, while 'nothing' can never exist; the possibles have a positive thought-content, while 'nothing' is a mere negation; the possibles differ among themselves, while between 'nothing' and 'nothing' there is no difference.

Kinds of Possibility. The main kinds are *intrinsic* and *extrinsic*. Extrinsic possibility is either 'physical' or 'moral.' *Impossibility* is the reverse of 'possibility,' and there are as many kinds of impossibility as there are kinds of possibility.

Chapter 7

ULTIMATE GROUND OF POSSIBILITY

THINGS ARE POSSIBLE BEINGS WHEN THEY HAVE A CAPACITY FOR existence. For a thing to be possible, two conditions must be present: the elements constituting its being must be compatible (non-contradictory), and that is 'intrinsic' possibility; and there must exist an efficient cause with sufficient power to bring the possible thing from non-existence into existence, and that is 'extrinsic' possibility. Extrinsic possibility presupposes intrinsic possibility; for no efficient cause can produce a thing, if the constitutive elements of this being are contradictory and cannot be realized together. The compatibility of the elements is thus an *absolute* condition; without it a thing is metaphysically and absolutely impossible. The existence of an adequate efficient cause is a *relative* condition; one sort of efficient cause may not have enough power to produce the thing in question, but a higher and more powerful cause might be able to produce it. In the verification of these two conditions we have the immediate or *proximate ground* of possibility.

At present we are concerned with the deeper problem of the final or *ultimate ground* of possibility. It is not a question now whether this or that thing has a compatibility of its

constitutive elements, or whether this or that efficient cause can produce this or that particular thing. It is rather the question:

Why have the possibles any intrinsic and extrinsic possibility *at all*? Why are constitutive elements *ultimately* compatible or incompatible, so that some things are intrinsically possible, while others are intrinsically impossible? What is the ultimate foundation for extrinsic possibility, not only for a particular possible being, but for *each and every possible reality*, whether it ever becomes existent or not? Even the existing realities are possible, otherwise they could never have received existence. The question, therefore, involves the ultimate ground of *all possibility*, independent of actual existence as present or absent.

We will first consider the ultimate ground for extrinsic possibility, and then that for intrinsic possibility.

ULTIMATE EXTRINSIC POSSIBILITY

We may as well state, without further ado, that the ultimate ground or foundation of all possibility is found in the Supreme Being, in the *nature of God*. No philosophic proofs for God's existence and His infinite perfection will here be adduced. It would take us too far afield.¹ In connection with the present problem God's existence and infinite perfection must be assumed as validly demonstrated. Granted, then, the existence and infinite perfection of God's nature, we are prepared to prove that the ultimate ground for all extrinsic

possibility is found in the *omnipotence* of God, guided by His infinitely perfect *intelligence*.

In stating this thesis, we do not intend to affirm that God's omnipotence is the sole efficient cause, thereby denying the efficient causality of creatural beings. Creatural beings are also efficient causes. They possess productive powers and do actually produce things by means of these powers; as such they are the proximate ground for the extrinsic possibility of the things they produce. However, a moment's reflection should convince us that they are not the ultimate ground for this possibility. Finite causes do not and cannot produce the *total reality* of their effects, so that they bring the complete being from non-existence to existence. That would be creation, and finite beings *cannot create*; they merely change one kind of being into another kind of being. The forces of nature never produce the *matter* of which things consist; matter is always presupposed in every kind of creatural activity and causality. This 'matter' must also be accounted for when there is question of the ultimate ground of the extrinsic possibility of the things which creatural beings produce.

Similarly, finite beings produce things through the mediation of their operative powers, faculties, energies. The energies of nature can be transformed from one kind into another, as when heat is transformed into mechanical motion and electricity into light. But here again, it is a question of accounting for the extrinsic possibility of this creatural *energy*. Though an existent reality, it also is limited and contingent in its very nature, and we are therefore compelled to look for the ultimate ground of its

own possibility. Matter and energy can no more produce themselves than any other thing can produce itself; consequently, they also demand an ultimate ground *outside themselves* for their existence. They belong to the class of beings which we call the 'possibles' and as such are not self-explanatory.

Finally, we must admit that there are far more things of the same kind which *do not exist* than those which do. There could be more men, animals, plants, metals, elements, protons, electrons, etc., than those which actually exist; there could also be more electricity, heat, magnetism, light, mechanical motion, etc., than that which is actually present in our existing universe. These things, though they do not actually exist, are possible; they *could exist*, taken absolutely and by themselves, even though there are no existing causes in the universe which could create them and thus bring them from non-existence to existence. Since the present causes in our universe cannot give them existence, although they are possible, the ultimate ground of their extrinsic possibility does not lie in the actual universe but in something *outside the universe*. For we must bear in mind that the question before us involves *all possibles*, whether actually existing or not. Hence, when it is a question of the 'ultimate' ground of all extrinsic possibility, i.e., when we look for the *ultimate efficient cause* which could bring all possible beings into existence, this power can only be found in a being which is outside and beyond all beings of limited power and causality.

While the number of creatural beings in the actual universe is limited, there is no limit to the number of non-

existing possible beings which are capable of existing, provided there be a cause sufficiently powerful to produce them. It must be obvious, however, that only a positively infinite power is capable of producing the negatively infinite number of possible beings. The reason is clear. Since all creatural beings without exception, whether existent or non-existent, demand an 'ultimate ground for their extrinsic possibility, the efficient cause which can give them existence must be an *existent cause* and it must be completely *outside the class* of creatural beings. If it were not an 'existent cause,' it could not give existence to the possibles; and if it were not 'outside the creatural class,' it would itself belong to the possibles and as such would again demand an 'ultimate' ground for its own possibility. But such an existent cause which is outside the creatural class and which possesses a positively infinite power of causality, is the Infinite Being, God. The causality of God, however, resides in His *omnipotence*. Hence, it is the omnipotence of God which is the ultimate ground of all extrinsic possibility.

All extrinsic possibility is thus seen to be ultimately grounded in God's omnipotence. But not in His omnipotence alone. The infinite *intelligence* of God also has an essential part in the possibility of things. If His intelligence did not direct and guide His omnipotence, this omnipotence would act *blindly* in its productive activity. But that is absurd. God, the infinitely perfect being, cannot act blindly and unintelligently in any of His operations: intelligence is a prerequisite condition for His omnipotence to act. Of course, it is the omnipotent power of God which exerts *causality*, and not His intelligence; that is why we do

not place the ultimate ground of extrinsic possibility in His intelligence. Nevertheless, the possible beings must be 'known' before they can become the object of His omnipotent causal action; hence, His omnipotence must be directed and guided by His intelligence, in order that things *can* have extrinsic possibility.

And thus we see that the ultimate ground or foundation for all extrinsic possibility is found in the omnipotence of God, guided by His infinite perfect intelligence.

ULTIMATE INTRINSIC POSSIBILITY

In order that beings be truly 'possible,' they must also be *intrinsically* or metaphysically possible. That is to say, their constitutive elements must be *non-contradictory*, mutually compatible. This raises the vital question: What is the ultimate reason and ground why some constitutive elements are compatible, thereby making a being intrinsically possible, while other elements are incompatible so that a being is intrinsically impossible? In answer to this question we propose to prove that *God* is the ultimate ground of all intrinsic possibility in things. More specifically, it is not God's omnipotence, nor His will, nor His intelligence, but His infinitely perfect *essence*, which is this ultimate ground.

God is the *ultimate* ground of all intrinsic possibility in the possible beings.

This must be so. We have just shown that God is the ultimate ground of 'extrinsic' possibility. But 'extrinsic' possibility has its foundation in 'intrinsic' possibility. This

'intrinsic' possibility of things, then, must also have its ultimate ground *outside* the entire class of possibles; because, being only 'possible,' they themselves cannot give to themselves constitutive elements which would be either compatible or incompatible. Consider the vast amount of 'possible' beings that do not exist and never will exist. As 'mere possibles' they are entitatively nothing. They could, however, absolutely speaking, receive existence, due to the omnipotence of God and the compatibility of the constitutive elements of their essence. If the ultimate ground for this compatibility or incompatibility were found in them, they themselves would be the cause, or reason, or principle, why some things are intrinsically possible and others intrinsically impossible. But an 'entitative nothing' cannot be the cause, or reason, or principle, of anything. The possibles are *subject* to the law of intrinsic possibility, regarding both their essence and their existence, and as such must *conform* to this law in order to be 'possible' at all. They cannot, then, be the cause, or reason, or principle, of this law. Consequently, there must exist some being outside the entire class of possible beings, which is the ultimate ground of their intrinsic possibility. That being, of course, is God.

If God were not this ultimate ground, and if this ultimate ground were in the creatural things themselves, it would mean that God's omnipotence would be *dependent on His creatures* for the exercise of its causality. Even God's omnipotence, as we will see shortly, cannot produce an 'impossible' thing. If the reason for this does not lie in Himself, but in the creatures, these creatures would *restrict*

His omnipotence in a definite manner. But that is an absurdity. Creatures cannot restrict the power of omnipotence. Omnipotence, thus dependent and restricted by outside beings, would *not be infinite* in its perfection and would, as such, not be omnipotence at all. Consequently, to affirm that the ultimate ground of intrinsic possibility rests in the possibles themselves and not in God, would be a virtual denial of God's omnipotence and of God Himself. We must conclude, therefore, that this ultimate ground exists in God.

God's *omnipotence* is *not* this ultimate ground.

Some philosophers, among them *William of Ockham*² (about 1280—1349), defended the doctrine that intrinsic possibility depends ultimately on God's power. It is true that, because things are intrinsically possible, God's power can produce them. But we cannot reverse the statement and say that things are intrinsically possible *because* God's power can produce them. This statement seems innocent enough. However, consider what it implies. Why would things be intrinsically possible, i.e., why are their constitutive elements compatible and non-contradictory? Because God's omnipotence can produce them. And why are other things intrinsically impossible, i.e., why are their elements incompatible and contradictory? The only answer can be, *because* God's omnipotence cannot *produce* them. The ultimate ground for intrinsic impossibility would thus be the *lack of power* in God. If God had more power, the impossibles would also be intrinsically possible. But that is patently false.

God possesses power in an infinite degree; therefore, no things should be intrinsically impossible, if it were merely a question of God's power. In that case it should be within God's power to produce a being which is finite and infinite at the same time, which exists and does not exist at the same time, which is rational and irrational at the same time, which is living and dead at the same time. But to make an assertion like this, means to invalidate the Principle of Contradiction and that means to destroy the foundation of all being and knowledge: skepticism must follow such a view.

Consequently, if we accept God's omnipotence as the ultimate ground for intrinsic possibility and impossibility, we face the following dilemma: either God *lacks power*, because He cannot produce certain things, and that is why they are impossible; or He can *produce contradictory beings*, because He is truly omnipotent, and then there are no impossible beings at all. In the first alternative we deny God's omnipotence and thereby God Himself, and in the second we deny the validity of the Principle of Contradiction and thereby destroy the foundation of all being and knowledge. Both admissions are fatal. We must, therefore, conclude that the ultimate ground of the intrinsic possibility and impossibility of things is not due to God's omnipotence.

God's *will* is *not* this ultimate ground.

It has been maintained that the fundamental reason, why some things are intrinsically possible and others intrinsically impossible, is due to the fact that God freely willed that some constitutive elements shall be compatible and others incompatible. He could just as well decide that

what is now impossible shall be possible and what is now possible shall be impossible. *René Descartes* (1596—1650), for instance, affirmed that God did not will that the three angles of a triangle should be equal to two right angles because He knows that they could not be otherwise; on the contrary, this is so, and it cannot be otherwise, because He willed that these angles be necessarily equal to two right angles. In a similar manner, $1 + 2 = 3$, because God wills it to be this way; but if He had willed it to be different, the sum of $1 + 2$ could equal any other number.³ In other words, intrinsic possibility and impossibility has its ultimate foundation solely in the free will of God. God, of course, will not change His decision, and all things thus remain without confusion as He has willed them from eternity.

Such a view, however, has *disastrous consequences*. It is true that possible things can receive existence, and thus become actual, only if God freely decides to give them existence, for without His will no creatural thing can exist. But it is a totally different matter to assert that on that account His free will can change the contradictory elements of an intrinsically Impossible thing into non-contradictory elements. Consider the results of such a view. If God willed, He could create a man who would be God and, though God, would be only a plant, and this human-divine plant could be devoid of all life and still be omniscient and more than omniscient. If God willed, He could make a being which could be more powerful than His own omnipotence and at the same time could be absolutely inert, inactive, and powerless. A doctrine which involves absurdities such as these refutes itself.

God's *intelligence* is *not* this ultimate ground.

If the intelligence of God were the ultimate ground for the intrinsic possibility of things, it would mean that the constitutive elements in the essence of things would be compatible and non-contradictory, *because* they are *known* by God; God's intelligent knowing would then be the real reason why the elements of the possibles are non-contradictory and why the elements of the impossibles are contradictory. While this view comes closer to the true solution of the possibles than the others, it is not the final answer.

Certainly, if God's intelligence cannot think of the constitutive elements of a thing as being compatible, then such a thing is impossible; and if He can think of them as compatible, the thing is truly possible. But that does not necessarily imply that God's intelligence *confers* compatibility or incompatibility upon these elements. As a matter of fact and principle, 'being' is *logically prior* to 'thought,' because thought, to be true, must conform to the thing thought of. Thought logically presupposes the thing which is the object of thought; and that, in this case, is the 'possible' being.

Intelligence, through its act of knowledge, does *not make* the object *intelligible*. Rather, intelligence can know a thing only because this thing possesses intelligibility in itself, i.e., because it is a 'being' whose essence is constituted of elements that are compatible and for that reason has a *positive content* which can become an object of thought. Intelligence merely perceives and recognizes this compatibility or incompatibility of the essential

elements as something which is present and then acknowledges the fact that the thing is 'possible' or 'impossible.' Such is the nature of knowledge and intelligence. From this it will be seen that intelligence, in thinking of a thing, presupposes its intelligibility; and the intelligibility of a thing presupposes the compatibility of the elements of its essence. Consequently, intelligence does not really make a thing to be 'possible,' and God's intelligence thus cannot be the *ultimate* ground of possibility.

God's essence is the ultimate ground of intrinsic possibility.

This follows as a necessary conclusion from what already has been proved. God must be the ultimate ground for all possibility. But neither His omnipotence, nor His will, nor His intelligence, is the ultimate reason why some constitutive elements are compatible and others incompatible in the essence of things, so that the latter are possible or impossible. The ultimate ground for this must lie, then, in some reality in God which is logically prior to His omnipotence and will and intelligence. This reality, however, can only be His essence. Therefore, His essence is the ultimate ground of all intrinsic possibility.

A possible thing is fundamentally a 'being,' an 'essence,' while an impossible thing is fundamentally a 'non-being,' a non-essence.' Now, 'being' ('essence') cannot have its ultimate ground in anything but 'being' ('essence'), because 'being' can proceed only from 'being.' Consequently, God's *being* or *essence* is the ultimate ground for the intrinsic possibility of things. Because God possesses 'being' to the fullness of infinite perfection, other things can obtain

'being' from Him, in a limited and participated degree. This does not mean that they emanate from God's essence in any way, but that they can be *creatural imitations* which He can *produce*. In as much, then, as creatures can be made by God in imitation of His own being' and 'essence,' they are capable of receiving existence from His omnipotence, through an act of His will, guided by His intelligence; and in so far, and *only* in so far, are they 'possible.' On the other hand, a 'non- being,' a 'non-essence,' a 'nothing,' is the antithesis of God's being and essence and as such can be no imitation of Him; for that reason it is incapable of receiving existence from Him, that is, it is 'impossible.' And this also explains why the *possibles are intelligible*, while the impossibles are unintelligible. The former, since they imitate the infinite essence of God, possess constitutive elements in their essence which are compatible and therefore conceivable. The opposite is the case with the impossibles, and that is the reason why we can only think of them as negations of 'being,' as things that involve a contradiction in their very idea; the impossibles are inconceivable.

God's essence, then, is the ultimate ground for all intrinsic possibility, just as His omnipotence, guided by His intelligence, is the ultimate ground for all extrinsic possibility.

We now also understand why the *proximate* ground for intrinsic and extrinsic possibility resides in the possible things *themselves*. Because a possible thing possesses compatible constitutive elements in its own essence, it is 'intrinsically' possible in itself; but it possesses such

elements only because it is a finite copy of the compatible essence of God. Similarly, because there exists a finite cause which has the requisite power to produce the possible thing, this latter being is 'extrinsically' possible; but the finite cause has the power of causality only because it is a finite copy of the infinite causality of God's omnipotence.

This also explains why a thing is intrinsically or metaphysically impossible when our concept of such a thing involves a *contradictory thought-content*. Our concepts, of course, do not influence the reality of things, so as to make them either possible or impossible. But God's essence is the ultimate ground of all *being and thought*, the ultimate foundation for all *ontological and logical laws*. Our concepts copy reality, and the laws of our thought follow the laws of being. Consequently, just as there can be no contradiction in the 'being' of things without them being thereby intrinsically and metaphysically impossible, so there can be no contradiction in our 'concept' of things without them being thereby intrinsically and metaphysically impossible: our concepts of things imitate God's concepts of things, no matter how inadequately, just as the being of things imitates the being of God, no matter how inadequately. If, then, our concept of a thing involves a real contradiction, this contradiction will also exist for God's intelligence, because the thing is in contradiction to His own essence and as such must be intrinsically and metaphysically impossible *in itself*: God, therefore, could never make it either extrinsically or intrinsically possible without contradicting His own intelligence and essence.

We thus see the inner nature of possibility and impossibility. Being and thought, actuality and potentiality, possibility and conceivability — all have their root, their foundation, their final reason, their ultimate ground, in the infinite fullness and richness of God's own being and essence.

SUMMARY OF CHAPTER VII

The problem before us is the *ultimate ground* of all 'extrinsic' and 'intrinsic' possibility.

1. *Ultimate Extrinsic Possibility.* Finite or creatural beings possess real causality, but they do not produce the *total reality* of their effects: 'matter' and 'energy' are always presupposed as existing; their causality can only change things from one kind of being to another. But 'matter' and 'energy' must also be accounted for, when it is a question of the ultimate ground of all extrinsic possibility, because they also belong to the class of 'possibles.' Besides, there are far more possible beings which never receive existence than those which become existent. Since the finite causes of the present universe cannot give them existence, the ultimate ground for their possibility must lie outside the universe — in God. But it is God's *omnipotence* which is the principle of His causality. Consequently, God's omnipotence is the ultimate efficient cause which makes all possible things capable of receiving existence. God's omnipotence, however, cannot work blindly, but must be guided by His intelligence. Hence, God's omnipotence, guided by His *intelligence*, is the ultimate ground of all extrinsic possibility.

2. *Ultimate Intrinsic Possibility.* The reason why the constitutive elements of some things are compatible and those of other things incompatible, is found in God. This reason cannot lie in the things themselves, because both the 'possibles' and the 'impossibles' are as such 'entitatively

nothing,' and thus they cannot be the reason for the compatibility or incompatibility of their elements. This reason must, then, be found in a being *outside* the whole class of 'possibles' and 'impossibles.' That being is *God*.

But God's *omnipotence* is not this ultimate ground. If it were, then the only reason why certain things are 'impossible' would be because He lacks the power to produce them; that is a virtual denial of His omnipotence.

Neither is God's *will* this ultimate ground. If this compatibility or incompatibility were the result of His will, then, provided He willed it, the 'impossibles' could become 'possible.' But this leads to absurd consequences, since He could then produce 'beings' which would also be 'non-beings' at the same time.

Neither is God's *intelligence* this ultimate ground. Things would be 'possible,' because He thinks them, and 'impossible,' *because* He does not or cannot think them. But the 'object' is always logically prior to the 'thought'; intelligence presupposes its object and merely recognizes the fact of compatibility or incompatibility.

God's *essence is the ultimate ground* of intrinsic possibility. That must be the ultimate ground in God which is logically prior to His omnipotence, will, and intelligence; but that is His *essence*. Besides, things are 'possible,' because they are a 'being'; things are 'impossible,' because they are a 'nothing.' And since 'being' can only be grounded in 'being,' God's infinite essence must be the ultimate ground for the essence of the possible things.

Things are, therefore, intrinsically possible, because their being is in some way an imitation of God's infinite

essence.

Chapter 8

CHANGE AND MOTUS

GOD, THE INFINITE BEING, IS PURE ACT, ABSOLUTE ACTUALITY. He is the 'most real being (*ens realissimum*), without any' admixture of potentiality. In Him there is, and can be, no 'becoming' of any kind, because He possesses the fullness of being all at once and always. Whatever He is, He is from eternity and in an infinite degree of perfection. Such is our idea of God. How far this idea is justifiable before philosophic reason, will be seen in theodicy, a separate department of philosophy.

Creatural beings are a compound of potency and act. They do not possess their complete being all at once and always. Even when they have existence, they are perfectible, determinable, actualizable, to a greater or less degree; as such they continually pass *from potency to act*. There is a constant 'becoming' in them and an uninterrupted *change*. This metaphysical notion of 'change' will now claim our attention.

THE CONCEPT OF CHANGE

We acquire the concept of 'change' from our daily experience. We sleep and wake; we labor and become fatigued; we are glad and then grieved; we are healthy and then ill; we are conscious and afterwards grow unconscious; we are young and vigorous and then become old and feeble; we live and die. And we observe similar happenings in the various beings in our environment. All things, we are convinced, undergo changes in some way. Plants and animals come into existence, develop, mature, and decay. The seasons change, and so do the physical bodies, the elements, the earth, and the stars. The *Eleatics* (6 and 5 cent. B.C.) denied the fact of change and considered it an illusion: there is but one reality and that is absolutely unchanging and unchangeable. *Heraclitus* (born about 530 B.C.) went to the opposite extreme. He maintained that there is no permanent reality at all: nothing 'is,' everything is in a state of continuous change or 'becoming' (πάντα ρεῖ). The truth lies in the middle. Things change; but there is an underlying, relatively permanent subject in which the change takes place.

What is change? *Change is the transition from one positive state of being to another.* There are three conditions required for a true and strict change or mutation: (1) A positive *starting-point* (*terminus a quo*, term from which). A thing can be said to 'change' only when it already exists and has a definite, positive state of being to begin with. It must be an actual being, with a potency for some new state or act. (2) A positive goal or *ending-point* (*terminus ad quem*, term toward which). Just as the changing thing begins as a reality in a positive state of

being and not in a state of nothingness, so it must also end as a reality in a positive state of being and not in a state of nothingness. It must end as an actual being, with a newly acquired state or act. (3) A *real transition* from one positive state of being into another positive state of being. The changing thing must really pass from a state of potency to act, so that it is a different sort of being in some way after the change has taken place.

Examples will make these points clearer. Let us take a piece of ice and proceed to melt it over a fire. The *solid* state of the ice is evidently a positive state of being for the water. The result aimed at as an ending-point of the process of melting is the liquid state of the water, and that is also a positive state of being for the water. The process of 'melting' is the 'transition': the water passes from a solid state (starting-point, *terminus a quo*) over into a liquid state (ending-point, *terminus ad quem*). The water has 'changed.'

If any of these three conditions be missing, the change is not a *strict change*; but it may be called a 'change' in a *wider* and *improper* sense.

Sometimes the 'starting-point' is not a positive state of being, but a state of non-existence: we would then have the production of a thing from 'nothing,' and that would be *creation*. The notion of 'creation' is so common in the discourse of men, that this fact alone warrants its introduction here. At any rate, the notion of 'creation' represents an *intrinsic change* in an *improper* sense of the term.

Again, it may be that the 'ending-point' is not a positive state of being, but rather a state of nonexistence: the result

would be, not a strict change, but *annihilation*. If God were to destroy the world absolutely, so that not a vestige of it remained in existence, it would be annihilated. This is also called an *intrinsic change* in an improper sense.

The third kind of a change in a wider or improper sense would be, if there were *no real transition* on the part of the being that is said to change. An example: I walk through the rooms of an art gallery and look at the pictures. As I turn my gaze upon them, each one changes from a 'not-looked-at' picture to a 'looked-at' picture. Does a real change occur thereby in the picture itself? Evidently not; nothing has happened to the picture itself through the mere fact of my looking at it, so that it would now have acquired a new act or state of being. I am the one who undergoes a real change through the act of sight, but the picture remains just what it was before. Another example. Unknown to me, a distant relative has died. I have lost a relationship, and in that sense I can be said to have 'changed.' But the only one who really changed is my relative who died; so far as I am personally concerned, no real change has occurred in me. Such instances represent an external or *extrinsic change in an improper or wider sense*.

We thus notice that the term 'change' is not always used in a uniform meaning. In a strict sense, the notion of change involves a positive starting-point, a positive ending-point, and a real transition from one positive state to another.

KINDS OF STRICT CHANGE

A strict intrinsic change or mutation may appear in any of the following ways: *Generation and Corruption*. Generation and corruption are two different aspects of one and the same change: it is the transition of a being from one kind of *substantial entity* into another kind of substantial entity. The difference between generation and corruption is this: the substantial change which makes the one substance cease to be is called 'corruption'; and the same substantial change which, by means of the corruption of this first substance, brings the new substance into being is called 'generation.' The new substance is always generated through the corruption of the old substance; the old substance ceases to be in order to give place to the new. There are not two changes involved in this process, but a single substantial change which corrupts the one while it generates the other. Hence, the axiom: the generation of one substance involves corruption of another. We observe this kind of change in the life and death of plants and animals. The chemical elements are assimilated in nutrition and become parts of living tissue and living function, partaking of the life of the plant or animal; but when the plant or animal dies, they again change from living substances to inanimate chemical elements. Every substantial change thus involves generation and corruption.

Augmentation and Diminution. This change is the transition of a being from one *quantitative* state to another. If the being increases in quantity, it is 'augmentation'; if it decreases in quantity, it is 'diminution.' This is a common occurrence among corporeal beings. A boy grows in stature in the course of youth; an acorn develops into a stately oak;

the muscles grow weaker in severe illness; light fades when the voltage of electricity drops in the filament of a bulb.

Alteration. It is the transition of a being from one qualitative state to another. The skin becomes tanned, when exposed to the sun in summer; iron glows, if heated to a high degree of temperature; water vaporizes to steam at + 212° F.

Local Motion. It is the change which occurs in the transition of a thing from one *place* to another. A train travels from Chicago to New York; a lady walks from her house to the store; a boy runs through the park; a ball is thrown through a window.

If we compare these various kinds of strict changes, we notice that generation and corruption are *substantial* changes, while the others only change the accidental condition of a being and are, therefore, *accidental* changes. A thing changes from one substance to another in an instant (for instance, from nonliving to living, from life to death); a substantial change is, therefore, an *instantaneous change*. On the other hand, augmentation and diminution, alteration, and local motion, are in their nature changes that progress in steps and stages, gradually and successively; for this reason they are successive changes.

Closely related to the notion of 'change' is the notion of *motus* or *movement*.' It represents one of the most important phenomena of nature and deserves special attention.

MOTUS

The idea of '*motus*' has an honorable history. It dates back to the earlier days of Greek philosophic thought. *Aristotle* analyzed and developed it and fixed its meaning in a philosophic sense. Christian thinkers, especially the medieval *scholastics*, took it over and gave it considerable treatment, especially in their discussions on the existence and activity of the Supreme Being.

The term '*motus*' (Lat., *motus*, Gr., κίνησις, movement), *in the technical meaning which it has acquired in ontology, cannot be adequately rendered into English. 'Motion' and movement' are derivatives of the Latin word motus, but their meaning is more restricted. 'Motion' is used for local change, change of position regarding place and space. 'Movement' though broader in connotation than 'motion,' has not the philosophic width and depth of the term motus, as we shall see. The latter term, motus, is taken from the obvious case of local change and then broadened in meaning to apply to other activities of somewhat similar nature, even to vital and intellectual activities. The best thing to do under the circumstances is to specify the meaning of motus and use this Latin form, employing the English term 'movement' as an alternative.*

Motus agrees partly in meaning with a number of concepts which we have discussed so far, such as 'act' (Lat., *actus*, Gr., ἐντελέχεια, ἐνέργεια), 'potency' (Lat., *potentia*, Gr., δύναμις) 'change' (Lat., *mutatio*, Gr., μεταβολή), 'motion' or 'movement' (Lat., *motus*, Gr., κίνησις); yet it differs in some respects from them all. This will be clear from the following explanations.

In its *widest* sense the term *motus* means any *activity* whatsoever, whether or not it involves a transition from potency to act. All creatural activity contains a transition from potency to act; but God's activity does not, because in Him there is no potentiality of any kind. Both kinds, whether divine or creatural, are called *motus* in this sense. Thus, God's thinking, willing, living, loving, creating, etc., are eternally present 'acts' without any admixture of potency. Living, thinking, knowing, running, eating, producing, seeing, feeling, etc., or any activity of pure spirits, men, brutes, plants, or inanimate things, take place by means of a transition from potency to act; they become 'actualized' through their activities. All these activities, whether of God or of creature, are *motus* in this widest use of the term.

In a somewhat narrower, though still in a *wide* sense, *motus* means any activity involving a transition *from potency to act*. This qualification excludes God's activities, but it still includes all creatural activity. Therefore, all activities of pure spirits, men, brutes, plants, and inanimate things, belong to this class.

In a *stricter* sense *motus* means any activity involving a transition from potency to act in a *corporeal being*, whether it be an instantaneous (substantial) or a successive (accidental) change. This class excludes the activities of pure spirits, because they are incorporeal, but it still includes the activities of men, brutes, plants, and inanimate bodies. To this class we thus refer the production and death of man, brute, and plant; any chemical change of substance. These are instances of a substantial change. As examples of

accidental changes belonging to this class of *motus*, the following physical activities are characteristic: heating, freezing, illuminating, magnetizing, electrifying, etc.; running, walking, sleeping, eating, etc.; seeing, hearing, feeling, tasting, digesting, etc.

In a *strict* and *proper* sense *motus* is any activity involving the transition from potency to act in a corporeal being *through successive stages*, i.e., it is a successive change in a body. This, therefore, excludes all bodily changes of an instantaneous character, namely, generation and corruption; such would be the origin and death of living bodies and every substantial chemical change. On the other hand, it includes every kind of quantitative augmentation and diminution, qualitative alteration, and local change *in a body*. Examples are: growing physically larger or becoming smaller; heat and cold, strength and weakness; color, pain, pleasure; riding, jumping, rolling, etc.

ARISTOTLE'S DEFINITION OF MOTUS

Aristotle defined *motus* or successive change in the following manner: *the act of a being in potency while still in potency*; or, the actuality of that which is potential, in so far as it is a thing that is potential.¹ This definition may seem obscure, but, like all of Aristotle's definitions, it possesses a marvelous compactness and philosophic precision. Perhaps the best way to reach Aristotle's meaning will be to take an ordinary instance of local movement.

A train is about to travel from Chicago to New York and stands ready in the terminal. Here are the elements of its

motus or movement: the starting-point (*terminus a quo*) is the station in Chicago; the goal or ending-point (*terminus ad quem*) is the station in New York; the passage or transition is the entire trip from the station in Chicago to the station in New York. Wherein does the change, movement, motus, consist? As long as the train stands in the station in Chicago (starting-point) it is not yet in motion. When it stands in the station in New York (goal, ending-point), it is no longer in motion. Both these terminal points mean rest, not motion. Motion begins, when it leaves the station in Chicago, and lasts until it has come to rest in the station in New York. The complete 'act' to be acquired is its *arrival* at the station in New York, and it will always be in *potency* for this act until it arrives there. While it stands at the starting-point (Chicago), it is in *complete potency* for this act; and when it has arrived at its goal or ending-point (New York), it is in *complete act*. While traveling along the rails, the train partly realizes its act, because it is on the way, and it realizes its act more and more until it has its complete act on arriving in New York. But because its act is but partly realized while 'on the way,' it is always still partly 'in potency,' because its act must be realized further; and it must continue to pass from potency to act, until it finally arrives at its destination. Hence, the entire trip is a partial act which will be fully realized in the complete act at the arrival of the train in New York; and the train is always in potency toward this complete act as long as it is on the way: its motus is thus seen to be the act of a being in potency while still in potency. In other words: it is the actuality of a

partly realized potency while still only partly realized and tending toward complete realization.

As will be observed from this explanation, Aristotle's definition, though technical, displays a very keen and profound understanding of the essential elements of *motus*, as exemplified in local motion. The definition, of course, is not restricted to local motion. It applies with equal precision to *any successive change* or transition from potency to act, as long as the activity in question takes place in stages, so that there is a gradual realization of the complete 'act' striven for. Whenever a change is instantaneous, *motus* or movement, as just defined, does not occur; but it may occur in the preparation for this instantaneous change. In every case of *motus*, therefore, there is the following sequence: Before the thing 'moves,' it is in potency for both the *motus* and the final actuality to be acquired by it; when it begins to be 'moved,' it is no longer in potency for the *motus*, but has already acquired it as an intermediary act; while 'moving,' it still remains in potency for the final and complete actuality to be acquired at the ending-point of its *motus*; when it has acquired its final and complete act, *motus* ceases, and the thing comes to rest as completely realized. If we desire to use the term in a wider sense, we may do so; but then we must define our term accordingly.

Our concept of *motus* will receive further clarification, when we consider the various classes into which it can be divided.

KINDS OF MOTUS

As there are naturally many kinds of acts or actualities which can be acquired by objects in the universe, so there must be different kinds of *motus* or transitional ways of acquiring them. We thus distinguish:

Immanent or Vital Activity. It is the activity through which a living being perfects *itself* and makes itself the goal for the acquired actuality or perfection. Such an activity does not tend to leave the agent, in order to actualize a being distinct from itself; rather, it begins and terminates in the agent itself, so that it is also the passive recipient of the perfection acquired through its activity. Nutrition, for example, is an immanent activity. This function assimilates foodstuffs, so as to build and strengthen the very body in which it resides and remains (Lat., *immanere, manere in*, to remain in) and has its being. Plant, animal, and human bodies have immanent action; they are the term or goal of their own function; they move and actuate themselves. Thus, too, the various sense-perceptions, thought-processes, will-acts, emotions, etc., are immanent activities.

Transient, or Transeunt, or Transitive Activity. It is the activity which tends to *change another object*, distinct from the agent, thereby making this other object the term or goal of the acquired actuality. Here the agent and recipient are two distinct beings. The agent influences and modifies the recipient, while the recipient is thereby influenced and modified; the agent has the producing action, while the recipient receives the produced effect. Thus, a hot radiator sends heat in all directions, raising the temperature of the

surrounding atmosphere; the steam in the boiler of a locomotive drives the wheels which propel the train along the tracks. Since the changes produced in bodies may be of a varying character, we distinguish between three kinds of transient activity: mechanical, physical, and chemical.

Mechanical action is the active tendency of a body to change the *local position* of another body. Cases in point: swinging a baseball bat, throwing a stone, pushing a cart, drilling a well, digging a trench, closing a window, etc. *Physical action* is the active tendency of a body to change the *qualities* of another body without changing its substance and nature. For example: heating a body, freezing water, tempering steel, Painting a picture, magnetizing a needle, illuminating a room, etc. *Chemical action* is the active tendency of a body to *change the nature* of another body by combining elements into a compound, or dissolving a compound into its elements, or changing one compound into another. For instance: the chemical action which combines hydrogen and oxygen into water; the electrolytic action which dissolves water into hydrogen and oxygen; the radioactive change of uranium into radium.

In all these kinds of activities we find Aristotle's definition verified, namely, "that movement (*motus*) is a realization, but an incompleted one; because a potentiality, as long as it is such, is by its nature uncompleted, and therefore its actual functioning — which motion is — must stop short of the completion: on the attainment of the end, the motion toward it no longer exists, but is merged in the reality." It is always the case of the act of a being in potency

while still in potency: *actus entis in potentia quatenus in potentia.*

SUMMARY OF CHAPTER VIII

The transition from potency to act in finite beings is effected by means of 'change.'

1. *The Concept of Change.* Change is the transition from one positive state of being to another. Three *conditions* are required for this: a positive starting-point; a positive ending-point; and a real transition from the one to the other. If any of these three conditions be missing, we have 'change' in a wider and improper sense: such are creation, annihilation, and extrinsic change.

2. Kinds of Strict Change. 'Generation' and 'corruption' are the transition of a being from one kind of substantial entity into another kind of substantial entity. 'Augmentation' and 'diminution' are quantitative changes, while 'alteration' is a qualitative change. 'Local motion' is the transition from one place to another.

3. *Motus.* In its *widest* sense, *motus* means any activity whatsoever, whether divine or creatural. In a wide sense, it is any activity involving the transition from potency to act; this excludes God's activities. In a stricter sense, it is any activity involving a transition from potency to act in a corporeal being; this excludes the activities of pure spirits. In a strict and proper sense, it is any activity involving the transition from potency to act in a corporeal being in successive stages.

4. *Aristotle's Definition.* He defines *motus* as the act of a being in potency while still in potency; the actuality of that which is potential, in so far as it is a thing that is potential.

5. *Kinds of Motus*. ‘Immanent’ or ‘vital’ action is that through which a living being perfects itself and makes itself the goal for the acquired actuality. ‘Transient,’ ‘transeunt,’ or ‘transitive’ action is the activity which tends to change another object, distinct from the agent. This transient action is ‘mechanical,’ when it is an active tendency to change the local position of another body; it is ‘physical’ action, when it tends to change the qualities of another body; it is ‘chemical’ action, when it tends to change the nature of another body.

Chapter 9

THE PRINCIPLE OF CHANGE

CHANGE AND BECOMING ARE UNIVERSAL OCCURRENCES IN nature. Finite things, as the name indicates, have only limited being. As such they are always in potency for further actualization and determination. The terms 'change' and 'becoming' are not identical in meaning. Every 'change' is a form of 'becoming,' but not *vice versa*. According to strict terminology, 'change' is the transition from one positive state of being to another positive state of being; 'becoming' is any transition from potency to act, even if it be from nonexistence to existence. 'Becoming' is, therefore, in itself, a wider term than 'change.' These terms, however, are often employed to mean simply a transition from potency to act, and it is in this latter meaning that they must be taken when we speak of the Principle of Change.

STATE OF THE QUESTION

The importance of this principle, from a philosophic standpoint, can hardly be overestimated. It reaches down into the very depths of thought and being, and thus deserves a careful study. Resting directly on the Principles

of Contradiction and Sufficient Reason, the Principle of Change is nothing more than the application of these two primary principles to the processes of becoming and change as observed throughout the realm of nature. This Principle of Change is usually formulated: '*Quid quid movetur, ab alia movetur*; whatever changes, is changed by another.'

'Change' here means the transition from potency to act, and it makes no difference whether this transition is a transition from non-existence to existence or from one positive state of being to another positive state of being: the principle or law applies with equal validity to both kinds of becoming. In the first case, the transition from non-existence to existence involves the production of the whole entity of the being from nothingness. In the second case, it involves the transition of an existing thing to a different kind of being; this sort of change presupposes an underlying subject in which the change takes place.

When a concrete, positive being undergoes a change, there is always an underlying potential reality, called the *subject* or *matter*, in which the change occurs, and a perfection or actuality, called the *form*, which is either gained or lost; and this change always ends in a new positive state of being for the subject, because it is now something that it was not before. In all such cases of change, as *Aristotle* points out, "whether of quantity or quality or relation or time or place, it is obvious that there must be some underlying subject which undergoes the change."¹ And he mentions the following methods in which change may take place: "(1) Change of shape, as with the

statue made of bronze, or (2) additions, as in things that grow, or (3) subtractions, as when a block of marble is chipped into a Hermes, or (4) combination, as in building a house, or (5) such modifications as effect the properties of the material itself.”²

The Principle of Change, as enunciated, has this specific meaning: Nothing ever passes from receptive potency to act except under the influence of another being which is already in act. Or, to put it in a different way: No being can bring itself from receptive potency to act. ‘Act’ must be understood here in its philosophic sense as any entity determining or perfecting a thing in its being.

In testing this principle and giving its proof, we may appeal either to *experience* or to the *analysis* of the elements contained in the principle.

PROOF FROM EXPERIENCE

Physical science subscribes to this axiom of philosophy with regard to *mechanical motion*. *Newton* (1642—1727) gave scientific expression to it in the first two of his famous laws of motion: “(1) Every body tends to persevere in its state of rest or of uniform motion in a straight line, unless it is acted on by an impressed force; (2) change of momentum is proportional to the impressed force and takes place in the direction of the straight line in which the force acts.” These laws express plainly the universal fact that *inertia* governs the entire inanimate world and that nothing will ever pass from a state of rest (which is a state of potency) to a state of motion (which is a state of actuality, and newly acquired),

without it being brought into motion through the activation of some other body already in act. A body in motion, after having been brought into motion, cannot even change its own motion; this change must come through the influence of some other outside force. This clearly shows that, concerning mechanical motion at least, the Principle of Change is true: Whatever changes, is changed by another.

Science treats of *potential* and *kinetic* energy. Potential energy is energy of position, as we observe it in lifted weights, coiled or stretched springs, compressed gases, chemical combinations (e.g., explosives), storage batteries, etc. Kinetic energy is energy of *motion*, as we see it in a falling pile driver, a ticking watch, a discharging rifle, a burning flashlight, etc. Potential energy can be transformed into kinetic, and kinetic energy into potential. But it always necessitates an outside force to make potential energy active; of itself potential energy will *always remain potential*, and it will never be transformed into kinetic energy without some other transforming agency. An example or two from nature will elucidate this.

A punch press in a factory is punching holes into a steel-plate. The punch die is worked by the machine, the machine by the belt, the belt by the shaft, the shaft by the flywheel, the flywheel by the crank arm attached to the piston rod, the piston rod by the steam, the steam by the heat; the heat is generated by the combustion of the coal, the coal obtains its potential energy from the sun, the sun obtains it from the stored-up energy of its atoms; and the atoms — Inertia is a universal attribute of matter. Things tend to assume a stable equilibrium and to remain therein. They possess the

potency of becoming something; but in order to change, they require the active agency of another thing. We can trace this process back to the primary and elemental forces of nature, such as gravitational and sub-atomic energy, which supply the dynamic activities of physical bodies. Whether these agencies are kinetic transformations of deeper potential energies, science cannot say, for they lie beyond the ken of human observation. But so far as experiment and observation reach, we see that potential beings must be actualized by beings which are already in act. Hence, whatever changes, is changed by another.

PROOF FROM REASON

If we subject the Principle of Change to an analysis of its constituent factors, we will see that it is a principle which is *universally* and *necessarily* true. To state it again: No being can pass from receptive potency to act except under the influence of another being which is already in act; no being can bring itself from receptive potency to act; whatever changes, is changed by another.

This must be so. For one thing, every act or perfection thus acquired is a *new perfection or reality* for the being which was first only in receptive potency for it. Every 'act,' in contradistinction to receptive 'potency,' means some positive reality or entity modifying the thing; the thing *changes* thereby; it *acquires* something; it is now different from what it was before the change; it is in a *new state*. It is impossible that the thing changed be the same after the transition from potency to act as it was before: because

‘change’ means to pass from one state *to another*. Hence, through this change an act is acquired which is some new positive reality or entity.

It is evident that this new actuality acquired by the potential being demands a *sufficient and adequate* reason for its arrival: there can be nothing without a sufficient reason. This is an absolute requirement, based, as we have seen, on the Principle of Contradiction. In virtue of this requirement, the newly acquired actuality must be accounted for down to the last vestige. In so far as a thing is without sufficient reason, it has no being at all and cannot exist. Hence, when a being passes from potency to act, this act is something in the order of reality, and the being acquires it through the process of its change, and there must be a full and adequate reason for its presence after the change.

It must also be evident that the potential being, passing from potency to act in the change, *did not possess this act before the change*. When is a being ‘in potency’? When it has the ‘capacity for something.’ In such a state it certainly cannot possess this act already; otherwise it could no longer be ‘in potency’ for it, i.e., it could no longer be able to pass from a state of potency *to obtain it*. ‘Potency’ means a state of passivity, of receptivity, of possibility. It means the absence of a certain actuality, but it means at the same time the aptitude and possibility of *receiving it*. However, it receives it precisely by means of its transition from potency to act, by means of the *change*. But if it receives it by means of this transition and change, it could not possibly have had it before the transition and change. Otherwise an open

contradiction is stated: the being *had* this particular actuality *before* the transition and at the same time *it did not have it*. It had it before the transition from potency, because that is here assumed and claimed; and at the same time it also did not have it before the transition from potency, because it really acquired this actuality only by having passed from potency to act in order to obtain it. Hence, the thing passing from potency to act could not have possessed the actuality before the change, since the opposite assumption is *contradictory*.

So far it has been established that every actuality acquired through change is a new reality or perfection; its presence after the change demands a sufficient and adequate reason; it was not possessed as such by the potential being before the change, but was acquired by means of the change. Going a step farther, we must see that the being which passes from potency to act *cannot give this act to itself*. This means that the potential being cannot itself be the complete and adequate principle for the newly acquired actuality: It cannot 'move' or change itself.

Under the conditions as given, the potential being is incapable of giving this actuality to itself. The reason is extremely simple: *no being can give what it does not have*. No being can acquire the identical thing that it already possesses; and no being can give, either to itself or to another, something which is not in its possession: if it already has it, it can no longer acquire it; and if it lacks it, it cannot give it to itself or to another. It follows then, that, while a being is in potency for an act, it is without it. A potency *minus* the act, however, is certainly less perfect

than the potency *plus* the act. The act, consequently, is a plus-amount over and beyond the potency as such, *something superadded* to it.

Now, there are only three conceivable possibilities to account for this new reality: it can come either from the potential being itself, or from some actual being, or from nothing. Consider these cases. The *potential* being itself cannot give the new reality to itself, as has just been pointed out, because no one can give what it does not have; it is, then, no sufficient reason for it. On the same grounds, '*nothing*' cannot be a sufficient reason for the appearance of the newly acquired actuality, because 'nothing' possesses nothing and thus can give nothing to the potential being. Therefore, the potential being, in acquiring a new actuality through the transition from potency to act, can receive it *only from some other actual being*. Here, then, we have a truly sufficient reason: this other being exists; it possesses the actuality and communicates it to the potential being by 'moving' or 'changing' it, by making it pass from potency to act. That alone is a satisfactory explanation and does no violence to reason.

From all this we must derive the necessary conclusion: *Whatever passes from receptive potency to act does so under the influence of some other being already in act.*

THOMISM AND THE PRINCIPLE OF CHANGE

The Principle of Change, as enunciated above, refers to a *receptive* potency. All scholastics are in agreement as to the validity of the principle in this respect. There are, however,

also *operative potencies* (faculties, powers); these, apparently at least, are capable of performing operations *spontaneously*, without the necessity of being activated by other agencies.

Given the proper conditions, the mere proximity of certain chemical elements is sufficient to bring about an interaction between them, resulting in a chemical compound endowed with properties quite distinct from those of the constituent elements. A change has undoubtedly occurred, but this change is due, to all appearances, to the elements themselves, and not to the influence of any other agency. Radioactive elements are particularly remarkable in their change. Irrespective of their surroundings, they undergo transmutations which are spontaneous in character, and no known physical or chemical agency can hasten or retard these transmutations which take place within these elements themselves. They certainly seem to 'change themselves,' due to their own intrinsic operative potencies.

When we turn to the investigation of living beings, *organisms*, the facts become even more obvious. Plants, brutes, and men, it appears evident, possess *spontaneity of action, self-movement*. The operations of vegetation, sentiency, and rational life are *immanent* actions, proceeding from the organism itself and perfecting it in its being.

This does not mean that organisms are not *influenced* by outside agencies; the opposite is true. The seeds of plants, in order to begin development, need the stimulation of soil, moisture, and warmth. The assimilative powers need the

stimulation of foodstuffs in order to become active. The leaves need the stimulation of light for the production of chlorophyll, starch, etc. In animals the senses require the presence of definite stimuli before sensation can take place. The central sense, imagination, instinct, and sense-memory must be aroused into activity by the action of the peripheral organs of perception. The intellect of man requires the presentation of an object to stimulate it into activity. The appetency of the brute and the will of man also need an object to exercise their function. In some way, therefore, these operative faculties require an outside agency in order to pass from potency to act.

Nevertheless, in all these instances, the presence of these stimulations and objects seem to be more in the nature of a *condition for self-activity* than a changing agency as such. We cannot, of course, deny the existence of activity in creatural beings, whether it be transient activity in inorganic beings or immanent activity in organic beings; such a denial would lead to the false theory of occasionalism. It seems equally obvious, too, that such beings are *spontaneously active* and pass from the potency of their faculties to the act of their operations by their *own agency*, and not through the agency of another being: they 'move or 'change' themselves.

Because of these considerations, many scholastic philosophers restrict the Principle of Change to the *receptive* potencies; the *operative* potencies are outside the scope of this principle and are not affected by it. *Thomistic* scholastics, however, claim that the Principle of Change applies with equal force and rigor to *receptive* and

operative potencies alike. The school of Thomism defends the view that 'nothing ever passes from potency, whether receptive or operative, to act except under the influence of another being which is already in act'; 'no being, under any conditions, can reduce itself from potency to act,' and this applies, therefore, also to the operative potency.

According to the view of modern Thomism, an *antecedent physical influence, or physical premotion (praemotio physica)*, is required in order that the faculty of a creature can pass from potentiality to actuality. It is only in virtue of this antecedent physical influence that the faculty is immediately capable of operation. This influence is supplied by God to all creatural activity.

On what grounds do the Thomists base their contention that the Principle of Change also applies to the 'operative' potencies? On the grounds that the Principle of Sufficient Reason absolutely demands their inclusion in the Principle of Change. There is, they say, no essential difference between a receptive' and an 'operative' potency, when it is a question of passing into act. An operative potency, such as intellect and will, is certainly *perfected* by its operation. By means of this operation, which is an 'act,' the faculty now possesses a perfection which was not present before; it is something superadded to the faculty, a plus-amount newly acquired. Since the faculty did not possess it before, it could not give it to itself; only an outside agency can, then, be adequate cause of this new perfection. The faculty itself as a 'potency' cannot be the sufficient reason for the acquisition of the new perfection contained in the operation as an 'act.' Hence, it cannot reduce itself from potentiality to actuality,

and the Principle of Change applies to the 'operative' potency with the same rigor as it applies to the 'receptive' potency. In other words, the Principle of Change is a universal principle without exception. And because of this, a physical premotion on the part of God is necessary in order that the operative potency or faculty can become active.

Those who disagree with the thomistic view in this matter fail to see the stringency of their argument. Especially, the theory of this physical premotion seems to them to be inadequate. They point out that such an influence only places the faculty in *immediate preparation* for the operation that is to follow; it does not communicate the actual operation itself, but makes the faculty 'capable' of action. But in that case, the faculty still must pass from potency to act; and that would be contrary to the Principle of Change, as interpreted by the Thomists. Then why should it not be possible for the Creator to endow the creatural being with a complete faculty capable of action without the antecedent physical influence? The latter seems altogether superfluous under the circumstances and incapable of performing the function ascribed to it by the Thomists. And if the Thomists were to assert that it is precisely this physical premotion which reduces the faculty from potency to act, then it would seem that the faculty is no longer an 'operative,' but purely a 'receptive,' faculty and as such has no operation of its own. But is that not tantamount to a denial of all creatural activity?

On their part, the opponents of Thomism have the difficulty of explaining the presence of the 'new perfection' of the operation as an 'act' perfecting the faculty. We must

uphold the Principle of Sufficient Reason; all admit that. On the other hand, it seems obvious that creatural beings are truly active in virtue of the intrinsic powers with which they have been endowed by the Creator. If the operative power needs an outside agency (a physical premotion) to reduce it from potency to act, then the same situation applies to this agency; it is also a creatural power and needs another agency to reduce it to act. But this involves either an infinite regress, or we must end the series by stating that God is the direct agent of all creatural activity; that, however, would be occasionalism, denying true activity to creatures, and this agrees neither with experience nor with the principles of sound philosophy.

How can we harmonize this view with the Principle of Sufficient Reason? The opponents of Thomism make a distinction between the *virtual act* and the *formal act*. The 'perfection' of the operation is precontained in the faculty as an effect in its equivalent cause. The 'change' which takes place, when a faculty passes from potency to act in its operation, is not a change in this perfection itself, but in the perfection's *manner of being*: from being a *virtual* act it changes to a *formal* act. The perfection of the operation as an 'act' is not contained 'formally' in the faculty; all are in agreement on this point. However, if this perfection of the operation were not pre-contained at least 'virtually' in the faculty, then the faculty would not be an 'operative' potency at all, but merely a receptive' potency; then we should drop the concept of an operative' potency entirely and deny the possibility of true creatural activity. Hence, in order to safeguard the Principle of Sufficient Reason and the natural

activity of creatural beings, we must maintain the presence of the *perfection* of the operation as 'act' in the faculty as 'potency'; the change, then, which takes place in the passage from potency to act is the change of the virtual act to the formal act. In this view, therefore, the Principle of Change applies strictly to the 'receptive' potencies, but not to the 'operative' potencies.

In a more limited way, and in a wider sense, the Principle of Change can also be said to apply to the *operative* potencies. This is done, for instance, by *Sylvester Maurus*: "The opponents seem to have understood this principle *negatively* as if the sense were that nothing is moved by itself; and against this they have instanced the actions of animals and other beings which move themselves. However, the sense of the principle is *affirmative* in intent. No one denies the something can move itself, concurring *partially* to its own movement: but we assert that no being can move itself *totally* and as *with perfect self-sufficiency*: it must be moved by another so that it can move itself. It will be manifest to anyone giving due consideration to these terms, that everything which is moved, that is to say, everything which is changed intrinsically, now possessing some entity and now lacking it, is not its own *total cause* of possessing or lacking it, but must be moved by another being which forces it, or entices it, or attracts it, or perfects it. Consequently, even the free will, being a created and mutable reality, though it is primarily the cause of changing itself, cannot change itself except in so far as it is moved to change itself through some object which attracts or entices it."³

The arguments of the Thomists and their opponents, as outlined above, are based on fundamentally different views concerning the nature of an operative potency. The reader must decide which view he considers to be more consonant with fact and principle.

COROLLARIES

From the above explanations a few simple *principles* concerning act and potency are clearly seen to flow.

In so far as a thing is in act, it is perfect. An act is an entity determining and perfecting a thing in its respective order. An act is the realization of a certain power, the natural complement of a potency. Thus, the intellect is a faculty, a power; its natural purpose is to understand, and thought is its act, its actualization. It is evidently more perfect actually to think than merely to be able to think. Similarly, sight as a power or faculty is but the capacity for seeing; actual seeing, or vision, is the act or determination of sight as a faculty, and it is more perfect to have actual sight than only capacity for it. Potency is the mere capacity for something, and an act is the perfection, the realization, of this capacity. From the reverse standpoint, then, the following principle is equally true: *In so far as a thing is in potency, it is imperfect.*

What, then, must be the most perfect being? A being that is purest actuality, one without the slightest potentiality, one which (who) has being to the utmost degree possible, intensively and extensively — God. And what is the most imperfect being? The one with most

potentiality. Spiritual beings are beings to account for the actuality contained in the universe. The multiplicity of beings in the universe might lead us to the conclusion that there must also exist a plurality of actual beings outside the universe and prior to it. However, if it can be shown that the world is really a universe and not a *pluriverse* (to employ an unusual term), this line of thought would lead to one being as the actuality postulated by the facts under consideration. That the world is really a 'universe' seems quite clear. Astrophysics has established the fact that the stars and the earth consist of the same chemical elements and are governed by the same mechanical, chemical, and physical laws throughout; the world is a co-ordinated system, a totality of beings united together into a real *universe*, a *cosmos*. Since this involves a unified plan of construction and of activity, the changes and developments in the universe point very definitely to *One Being* as the agent responsible for the actuality acquired anywhere throughout the vast expanse of the present cosmos as we know it. And since an infinite regress in potential beings is impossible, and since even an infinite series of potential beings would demand an actual being outside the series itself, there must actually exist a *Prime Mover Unmoved* possessing complete actuality without any admixture of potentiality. If this Prime Mover again had any potentiality, this would also presuppose another actual Being preceding it, and so on backward, until we arrive at the First Being who is the real Prime Mover Unmoved, capable of conferring actuality on *all* potential beings without exception by assisting them in their transition from potency to act. These secondary

beings can be active only in co-operation with the Prime Mover.

There must, then, exist in the real order a Being who is *Pure Actuality*. We call this Being *God*. God, therefore, is not a mere abstraction, something like 'being in general,' devoid of all real content, but *Supreme Reality and Power*. He is in all truth the First Principle of thought and being, and as such He is, if we understand the term in its fullest and richest meaning, the *Absolute*.

Furthermore, the implications of the Principle of Change show the futility of the attempt of *Hegel* to deduce all things through the *logical evolution* of the concept of 'being.' The concept of 'being,' with which Hegel begins, is not the concept of God as Pure Actuality; it is the concept of 'being in general,' so empty of all real content that he considers it absolutely void and equal to 'nothing.' As he himself states: "Being is not a particular or definite thought, and hence, being quite indeterminate, is a thought not to be distinguished from Nothing."⁴ But 'being' does not remain in this indeterminate condition; it 'becomes,' and through this becoming it evolves into all determinate being, into nature and spirit and eventually into the Absolute. "Becoming is the first concrete thought, and therefore the first notion: whereas Being and Nothing are empty abstractions."⁵

This 'becoming' then gives rise, according to Hegel, to 'determinate being' in the following interesting process of logical evolution: "Even our ordinary conception of Becoming implies that somewhat [something] comes out of it, and that Becoming therefore has a result. . . . Becoming

always contains Being and Nothing in such a way that these two are always changing into each other, and reciprocally cancel each other. Thus Becoming stands before us in utter restlessness —unable, however, to maintain itself in this abstract restlessness: for since Being and Nothing vanish in Becoming (and that is the very notion of Becoming), the latter must vanish. . . . The result of this process, however, is not empty Nothing, but Being identical with the negation — what we call Being Determinate (being then and there’): the primary import of which evidently is that it *has become*.”⁶

In evaluating Hegel’s views, as given above, we must remember that he was actuated by the purpose, laudable in itself, of effecting a *supreme synthesis*. But in this endeavor he was misled into attempting to synthesize ‘thought’ and ‘thing’ into the ultimate ground of ‘being in general,’ of abstract and indeterminate being; he thereby hoped to harmonize not only the conflicting elements of ‘being,’ but also the contradictions or antinomies of ‘thought.’ Hence his contention that all ‘being’ is thought ‘realized’ and all *becoming is a logical development*. He therefore begins with the *idea* of ‘being’; and since this idea is also the *reality* of ‘being,’ it actually develops itself from indeterminateness to determinateness (‘determinate being’) by means of an *eternal logical process* of internal evolution. At first ‘being’ is so indeterminate that it is equivalent to ‘nothing,’ but through this process of logical ‘becoming’ it gradually unfolds itself into every kind of determinate being: it is a process of *self-actualization*.

This, however, is an *essential error* in Hegel's idealistic monism, because it is in contradiction to the Principle of Change (Becoming), as shown above. From both a logical and ontological viewpoint, Hegel's 'Being' is incapable of evolving in this manner. As a *logical* entity, his 'Being' is abstract, indeterminate, empty of content, equivalent to 'Nothing.' Since it contains nothing, nothing can arise out of it; hence, 'determinate being' can never be deduced from it. As an *ontological* entity (supposing it to be such), it is devoid of all actuality and therefore purely potential. This 'Being' does not contain all actuality in itself like coins in a purse or peas in a pod; it is rather, according to Hegel's own statement, "empty Nothing."⁷

Consequently, this 'Being' must be pure *potentiality*. It develops into all determinate being, not through some other being distinct from itself (for how can there be any being outside the whole class of 'being?'), but by means of the intrinsic *self-actualization* of its potentiality. But this is unintelligible and impossible. Since 'Being' contains no actuality, it cannot give any actuality to itself, because no one can give what one does not possess. And this 'Being' cannot receive it from another being, because outside the totality of 'Being' there is only 'Nothing,' and 'Nothing' has nothing to give. If, then, Hegel's contention were correct that the origin of all things comes from indeterminate 'Being,' which is equivalent to 'Nothing,' no determinate beings could ever come into existence. But the *universe is here*. Hence, it did not originate from this abstract, empty 'Being,' and Hegel's monism must be rejected as inadequate and false.

Finally, the Principle of Change shows conclusively that no theory of complete *evolution*, whether mechanistic or vitalistic, can fully explain the origin and development of living beings and of the world at large. The very idea of evolution involves change and development. It means the unfolding of forces in the direction of beings possessing more complicated structures and *higher forms* of organization from a more or less primitive and amorphous state. This implies a movement of an upward trend, with a constant and gradual acquisition of *higher perfection*; it is a transition from potency to act on a world-wide scale, an *actualization* which becomes more complete in the course of the ages. Such an evolution, however, if it took place, could never occur in virtue of the inherent forces of nature alone. There must be an actual Being outside this whole process of evolution, to activate these forces and give them direction toward higher actuality: whatever changes, is changed by another.

It makes little difference whether we accept mere matter and force as the moving principle of evolution, as the materialists do; or whether we claim that all matter is endowed with psychic activity, as the pan-psychists do; or whether we postulate some 'mind stuff,' which later develops into mind and matter, as the neutralists do; or whether we attribute evolution to a general vital impulse (*élan vital*), as Henri Bergson and his followers do; or whether we assume a *nisus* as the driving power of evolving new and unpredictable qualities, as the advocates of 'emergent evolution' do; or whether we take 'space-time' as the matrix of all evolving reality, as S. Alexander and some

relativitists do: evolution in every form starts with potentiality and progresses toward actuality. Even though evolution should be proved to be a fact, the Principle of Change would still necessitate the *prior existence of a Prime Mover* to account for the presence of evolution in the universe. Any other supposition would leave the entire process without a sufficient reason to explain the change and as such would involve a contradiction.

Such, then, is the Principle of Change (Becoming) in its nature and in its consequences. No being, subject to change, can escape its influence, It applies with equal force to things in the material and in the spiritual order of being. As a metaphysical principle, it will be noted, it is linked very closely with the ultimate foundation of possibility.

SUMMARY OF CHAPTER IX

The term 'becoming' means the transition from potency to act; 'change,' in the strict sense, means the transition from one positive state of being to another. But here we take 'change' in the wider sense of 'becoming,' when discussing the Principle of Change.

1. *State of the Question.* The Principle of Change reads:

Whatever changes, is changed by another; or, nothing ever passes from receptive potency to act except under the influence of another being already in act; or, no being can bring itself from receptive potency to act. In every change the result is the acquisition of a *new state* of being.

2. *Proof from Experience.* Physical science acknowledges this principle regarding mechanical motion, as can be seen from Newton's laws of motion. The principle of *potential* and *kinetic* energy also shows that potential energy cannot become kinetic except under the influence of the active agency of kinetic energy, because *inertia* is a universal attribute of all matter. Even the *vital powers* of organisms cannot become active unless stimulated into activity by other agencies; at least they are not the *total* cause of their self-movement.

3. *Proof from Reason.* Every act acquired through change is a new perfection or reality; this new reality demands a *sufficient* and adequate reason; this sufficient reason does not lie in the potential being, because it does *not possess* it before the change; since this new reality is something superadded to it, it can only receive it from

another being already in act. Hence, no being can pass from receptive potency to act, except under the influence of another being already in act.

Thomistic scholastics apply the Principle of Change in all its rigor also to 'operative' potencies and postulate a physical premotion to assist a creatural faculty in its passage from potency to act; this influence is supplied by God. Other scholastics oppose this view on the grounds that such a physical premotion, as described, would destroy all genuine creatural activity and lead to occasionalism; they maintain that the perfection of the act is contained 'virtually' in the faculty, and the change consists in the virtual act becoming a 'formal' act.

4. *Corollaries*. In so far as a being is in act, it is perfect; and in so far as a being is in potency, it is imperfect. In so far as a being is in act, it is a principle of activity; in so far as a being is in potency, it is passive. From the act we can validly conclude to the operative potency; but from the operative potency we cannot conclude to the act. In the real order, act (actual being) must precede potency (potential being).

5. *Application*. Since all beings in the universe undergo change, the universe itself is essentially potential in many respects. And since the world is really a universe, not a *pluriverse*, it demands a Prime Mover Unmoved, who is Pure Actuality and as such necessary to assist all beings in their transition from potency to act.

Hegel's monism is thus seen to be impossible. He attempts to deduce all beings from the idea of 'being in general.' Since 'being in general' is entirely potential, its

self-actualization into ‘determinate being’ is contrary to the Principle of Change. Even if the present universe were the result of *evolution* in some form, a Prime Mover would be required. The very fact of an evolution from a primitive state to a condition of higher organization and perfection involves the transition from potentiality to actuality; this process of change demands an existing Actual Being prior to it, giving it direction and actuality.

Chapter 10

ESSENCE AND EXISTENCE

ESSENCE AND EXISTENCE ARE CLOSELY RELATED TO POSSIBLE and actual being, and as such also to potency and act. A possible being is one which has a capacity for existence, without having come into existence. An actual being is one which has existence, its capacity for existence having been realized. Existence is an act, a determination, a perfection. A 'possible' being is in potency for the existential act, while an 'actual' being is in possession of the existential act. A possible being can exist, and an actual being does exist. A deep and subtle problem lies at the root of essence and existence; hence, an examination of these fundamental realities will not be amiss.

ESSENCE

To arrive at the knowledge of the essence of a thing is a very difficult task, and it is seldom adequately accomplished. Psychology shows that the natural and proper object of knowledge for the human mind is the material thing, the 'sensible.' The channels through which the material thing reaches the mind are the bodily senses —

sight, hearing, touch, and so forth. The senses perceive only the accidental properties of things. We cannot perceive the essence of things with our senses; we can only infer the essence from the accidental properties by means of our intellect. We must analyze all our knowledge of a being, until we arrive at those elements which are absolutely required and which absolutely suffice to make that being to be just what it is, distinct from any other similar or dissimilar thing. These elements are its essential notes, its essence. Hence, *essence* is defined as *that through which a being is just what it is (id quo res est id quod est)*.

What, for instance, is the essence of man? That which makes him to be simply and positively a 'man,' and not a brute beast or a plant or an inanimate object or anything else. 'Animality' and 'rationality' are found in every individual 'man' and distinguish him from every other being in nature. His animality places him in the genus of 'animal,' and his rationality is the specific difference which places him in the species of 'man' as such. It will thus be seen that the definition of a being according to *proximate genus* and *specific difference* is equivalent to designating the essence of a being. For this reason *St. Thomas Aquinas* defines essence as "that through which a being is placed in its proper genus or species and which we signify by means of a definition indicating what a thing is."¹

Every being consists of essentials and non-essentials, when found in the natural order of the universe. Whatever is present in a thing is 'being'; not 'being' in the wide and abstract sense of 'being in general,' but rather definite degrees and determinations of entity in a *concrete* manner.

A man, as he actually exists, is not merely some indefinite and indeterminate being; he is a concrete being which consists of a definite amount of corporeal, living, sentient, rational substance and which has definite size, weight, shape, color, sex, and all those manifold powers of operation that we observe in our lives. And for all this complex amount of entity there must be a common source and fountainhead of being and operation. This source we appropriately designate the thing's *essence* (Lat., *esse*, to be; *essentia*, being), because it is the ultimate principle in the thing from which it derives whatever it possesses in the line of 'being' in any form.

Philosophers express the essence in various terms, depending on a difference of viewpoint. The essence of a thing is sometimes called *nature*. Out of the essence as out of a matrix all being of a thing is, so to say, born (Lat., *nascor*, to be born; *natus*, born; *natura*, nature); the elements of a thing, which constitute its being, have existence only in so far as they flow (are born) from the essence. Specifically, 'nature' is an essence considered as the ultimate principle of operations in a being. Man, for example, increases in weight and size, digests food, feels pain, thinks, and wills; but all these operations flow from his essence as a 'rational animal' as from their ultimate principle.

The essence of a thing is also called *quiddity* (whatness). This term is derived from the Latin word *quidditas*, which is a technical noun made from *quid* (what). The reason is obvious. When we desire to know what a particular thing really is, we ask the question 'What is it?' And in answer to

this question we obtain a knowledge of its 'whatness'; because, in being told what it is that makes this thing to be just this being and not another, we find out its essential elements (essence) in the definition given.

Oftentimes, too, the essence of a thing is designated as its *substance*. Every creatural being is a combination of 'substance' and 'accidents.' This pair of concepts will receive special treatment later; for the present it will suffice to show why the term 'substance' is used for the term 'essence.' The substance supports the accidents in their being and existence. Iron, for example, has many qualities and properties, like weight, extension, solidity, fusion point, color, etc., but these accidental determinations cannot exist except in the body of the iron; the body or 'substance' of iron is thus seen to be the principle from which such accidents flow and in which they have their being. Hence, the substance is the primary reality in a thing, while the accidents are only secondary realities in it. However, the primary reality in any being is its essence; and that is the reason why the 'essence' of a thing is often called its 'substance.'

The designation of essence as 'substance' can, however, be ambiguous and lead to confusion of thought. We have seen that 'essence' is defined as that which makes a being to be what it is. Accidents, too, are beings, things, realities; and as such they contain within themselves elements which make them to be what they are: weight to be weight, extension to be extension, thought to be thought, motion to be motion, and so forth. Each accident has an 'essence,' taken by itself, which makes it to be just this sort of accident

as distinct from every other. When, however, we look for the essence of any concrete *individual*, considered as a substance endowed with certain accidents, then, of course, it is the 'substance' of this individual which constitutes its essence. Generally speaking, therefore, it is correct to say that the essence of a thing is its substance. The context of the discussion will reveal whether the term 'essence' applies also to accidents.

CLASSIFICATION OF ESSENCE

There are two main kinds of essence, because we can view essence from two fundamentally different standpoints: from the standpoint of its *concrete* existence in the physical world, and from the standpoint of its *abstract* conception by the mind in thought. Correspondingly, we speak of physical and metaphysical essences.

Physical essence is an essence as it exists *concretely in nature*, independent of the mind's thinking. Such an essence is taken objectively, and thereby we mean the sum of those fundamental elements which, in the natural order of the world, constitute the object's innermost being, no matter how our mind may conceive them in its thoughts. Man, for instance, consists of two essential principles in his physical nature, namely, body and soul. The same is true of animals and plants; they, too, consist of a body and a life-giving principle. These various classes of living beings are composed of the same chemical materials (matter) as the determinable element of their physical being; that plants and brutes and men differ so greatly among themselves is

due to their determining life principle (form, soul) which uses this common material according to the needs of its specific nature. These elements or principles constitute the essence of a thing in the *concrete physical* order, irrespective of any mind that may contemplate them, and hence such an essence is called a 'physical' essence.

If such a physical essence is simple, i.e., constituted by a single substantial principle, and not by two or more substantial part-principles, it is a *simple* physical essence. God's essence and that of pure spirits are one in nature and not compounded by two or more substantial parts. But if this essence is composite, i.e., if it consists of two or more substantial part-principles (like body and soul), which together constitute one complete nature, it is a *composite* physical essence.

Metaphysical essence is the sum of the various *grades of being which constitute a thing in the abstract concepts of the mind*. Here we do not consider an object as it exists concretely in the physical world, but according to the manner in which it is conceived by the mind. An example will clarify this, In the physical order of existence, man is a compound of body and soul; notwithstanding this composition, he is a single being or essence. When the mind conceives man as a 'corporeal, living, sentient, rational substance,' the mind is fully aware of the fact that he does not consist of one physical part which is his substance,' and of a second physical part which is his 'body,' and of a third physical part which is his 'vegetant life,' and of a fourth physical part which is his 'sentiency,' and of a fifth and final physical part which is his 'rationality.' Man is a substance,

and this substance is at one and the same time corporeal and living and sentient and rational — one reality expressed in five objectively different concepts, like a set of photographs taken of the same person from five different angles. The five concepts, taken alone by themselves, give but a partial and inadequate idea of the one essence; taken together, however, they supplement each other and give a correct and complete idea of man's essence. The mind must represent the one reality by means of five objectively different concepts, because it is incapable of expressing it in a single all—comprehensive concept.²

Such parts of an essence which are the 'grades of being' of one concrete nature (in reality identical and inseparable, but distinct and separable in thought) are called *metaphysical parts*; and the essence which is conceived by the mind as consisting of such metaphysical grades of being is called the *metaphysical* essence of the thing. Needless to say, it is possible to express a number of such metaphysical grades of being by means of a single term. A corporeal substance is termed a 'body'; a living corporeal substance is termed a 'plant.' A sentient, living, corporeal substance is termed an 'animal.' A rational, sentient, living corporeal substance is termed a 'man'; and a man is often termed a 'rational animal.' A glance shows us that this latter mode of expression is the definition of man according to his proximate genus and specific difference. Whichever way we express the essence of a thing, whether by an enumeration of the single grades of being or by a definition according to the proximate genus and specific difference, in either case we express the *metaphysical* essence of that thing.³

PROPERTIES OF METAPHYSICAL ESSENCES

Metaphysical essences possess a number of properties: they are immutable, indivisible, necessary, and eternal.

Essences are immutable. The sense is: no constitutive element can be subtracted from, or added to, an essence without destroying the essence itself; any essence will cease to be that particular essence, if an element is added to it or subtracted from it. An essence is that which makes a thing to be what it is. To add another essential element to such an essence, or to take an essential element away from it, would mean that the thing would no longer be what it is. For a man to be a 'rational animal;' is his whole essence; that makes man to be precisely a 'man.' If 'rationality' were removed from the concept of man, only 'animality' would remain; but 'animality' alone does not constitute man's essence, and man would no longer be 'man.' Similarly, we cannot add any constitutive elements to an essence. A brute's essence is a sentient, living, corporeal substance; it does not possess 'rationality.' If we add 'rationality' to the brute's essence, it would be a 'rational animal'; thereby it would cease to be a brute and would now be a man. A man's essence, however, is always that of a 'rational animal,' and a brute's always that of a 'non-rational animal': they cannot be changed without ceasing to be what they are. Hence, metaphysical essences are immutable.

Essences are indivisible. A metaphysical essence, as we have seen, may consist of a number of grades of being. These grades of being, however, are not separable physical parts or entities; of the contrary, they are inseparably fused

together into a single, identical substance. Hence, it is impossible to divide them. Were it possible to divide them, they would be separable one from the other. Since essences are immutable, such a separation and division cannot take place without destroying the essence itself. For the same reason no essences are present in unequal amounts or degrees in individuals of the same class. Thus, all men have 'humanity' in the same degree; no individual is 'more man' than another: human nature and human essence is everywhere alike. The same is true of any other kind of being belonging to a definite class, such as lions, eagles, roses, trees, gold, radium, carbon, and the like.

Essences are necessary. This, of course, does not apply to essences in so far as they are found in the actual order of existence as physical things; as such they are clearly perceived to begin and to cease to exist. Individual men, brutes, and plants, for example, live and die; they have no necessary existence. Necessity, as applied to metaphysical essences, means that they must consist of their respective constitutive elements and of no other. Man's essence, for instance, must be that of a 'rational animal,' and it can never be anything else. Did the fact that man is a 'rational animal' ever have a beginning, or can it ever change? Evidently not. Under no circumstances or conditions can man be anything but a 'rational animal'; if he is not that, he is some other being, but he is not a 'man.' Hence, the content of metaphysical essences is a necessary content.

Essences are eternal. This follows from the foregoing. All that is meant by this is that the elements of an essence must be considered as constitutive of that particular essence,

without regard to past, present, or future. That the essence of 'man' consists in his being a 'rational animal' is something which has always been true, is true now, and will remain true forever. Man is simply such an essence, and he can be nothing else. In the idea of God man is just that; and since His ideas are eternal in their content, it is necessarily and therefore eternally true that man is a 'rational animal.' And what is true of man's essence, is also true of every other essence. Metaphysical essences are independent of time.

The unwary mind may become confused in this application of the idea of eternity to essences. It might think that somehow these metaphysical essences exist and possess an eternity of 'existence.' Nothing is farther from the truth. So far as actual existence is concerned, they are nothing. Only God is immutable, indivisible, necessary, and eternal in actual existence. An explanation of 'eternity' will elucidate this.

Eternity is duration without beginning, end, or change. It may be positive or negative. *Positive* eternity is a duration without beginning, end, or change in existence. This is 'real,' when it refers to actual existence; or 'ideal,' when it refers to possible existence. *Negative* eternity is the indifference of a thing toward existing in a determinate portion of time. Thus, we exist at this very moment; but there is no reason why God could not have called us into being at any other time in the past or future: we would simply exist then, and not now. From the above it will be clear that abstract, metaphysical essences possess an ideal and negative, but not a real, positive eternity.

To sum up: metaphysical essences, considered absolutely, as abstractly conceived by the mind according to their constitutive elements, have a content which is immutably, indivisibly, necessarily, and eternally the same. Physical essences, however, when actually existing in the physical universe, have no immutable, indivisible, necessary, and eternal existence; this will become more clear after an examination of the character of existence.

EXISTENCE

The essences, as just treated, were considered as abstract, metaphysical essences; they were not considered as they are found in actual existence. What is 'existence'? This is a primary and fundamental reality which cannot be adequately defined, but only known and recognized as the reality it is. Only those realities can be adequately defined, as logic shows, for which we can adduce a proximate genus and a specific difference. This, however, is not possible for a reality like 'existence.' The only proximate genus that could be used in its definition would be the idea of 'being'; but 'being,' as has already been observed, is no genus in the strict sense of the term. 'Being' can be applied only in an analogous meaning to its inferiors. The best that can be done, therefore, is to obtain a fairly accurate concept of existence by means of a description of its characteristics.

As long as an essence is contained merely as a thought-content in a mind ('intrinsic' possibility) and contained potentially in the producing power of its cause ('extrinsic' possibility), it is still non-existent. When, however, through

the agency of the producing cause, such an essence ceases to be merely in a mind as a 'thought-of' essence and in its cause as a 'possible' essence, it is said to 'exist.' A cause, producing an essence in this manner, gives it 'existence.' *Existence, then, is that state of a being in virtue of which it is present as an actuality, and not merely as a possibility, distinct from the mind and, if it be a produced being, distinct from its producing cause.*

When a thing 'exists,' it is a part of the visible or invisible world of beings. Hydrogen and oxygen, when not united, exist as hydrogen and oxygen and are only potentially water; but when united, water exists, and hydrogen and oxygen are only potentially there. A thousand years ago none of us actually existed; we were, however, potential beings in our forebears and in the creative power of God. Now we are conscious of our own identity as apart from the causes which produced us; we are, therefore, conscious of our 'existence.' It is thus far easier to point out existing things and recognize 'existence' concretely in this way, than it is to explain 'existence as such' in words.

The concepts of 'essence' and 'existence' are closely related, especially in an actually existing being. The attempt to specify the exact character of the distinction between the two has been the occasion for one of the most protracted controversies in philosophy.

THE PROBLEM OF ESSENCE AND EXISTENCE

It is obvious that there is a distinction between 'essences and 'existence,' when we speak of creatural beings. In them

their essence *receives* existence, because they obtain existence through the agency of their producing causes. Their essence is not the ultimate ground of their own existence. If it were, they would have existence in virtue of their particular essence, and then, their essence as such being eternally what it is, they would of necessity possess an eternal existence. That, however, is not, as a matter of observed fact, the case: things begin to exist and cease to exist. Only in God is the essence the ultimate and full ground of His existence. God's essence, being infinitely perfect, includes existence. In Him essence and existence are absolutely identical. Hence, He possesses an immutable, indivisible, necessary, and eternal existence in reality. God simply *is*. In Him there is no potentiality of any kind; He is Pure Act. That cannot be said of finite, creatural beings; they are a mixture of act and potentiality. In their case, existence is to their essence like a determining act to a determinable potency.

Just *what* and *how great* is the *distinction* between essence and 'existence' in an actually existing finite thing? That is the problem. The point at issue is this: Is the distinction between the essence and existence in an actually existing object a *real* or only a *virtual* distinction? First of all, therefore, it will be necessary to understand when a distinction is 'real' and when it is only 'virtual.' The subject of distinctions in their various forms will receive a fuller treatment later; at present, it will be sufficient to restrict our explanation to the two forms of distinction just mentioned, because they are the ones which are involved in this problem.

Objects are *really* distinct, when they are distinct from each other in *entity* and in *concept*. Not only are their respective concepts (definition and comprehension, thought-content) different, so that the concept of the one does not include that of the other, but they are also different in their entity, independent of any mind and its thinking. The mind does not make the distinction here, but merely recognizes the difference which was present in the objects before ever the mind directed its attention to them.

Things are *virtually* distinct, when they are distinct from each other in *concept*, but *not in entity*. They are distinct in concept (definition and comprehension, thought-content), so that the concept of the one does not signify the same content as that of the other; but they are not different in their entity as they are found *in nature*. In nature there exists but one reality, and the mind makes two or more distinct concepts of them.

There is a real distinction between an essence in the 'possible' order and the same essence in the 'actual (existing)' order; because, so long as it is merely possible it is actually nothing, while in the actual order it is a real being among physically existing things. There is no problem here. But, taking an object as it is present here and now *in the actual order of physically existing things*, as it stands here and now *outside the mind and outside all producing causes*, is there a *real* or only a *virtual* distinction between an essence and its existential act (existence)? In other words: Are essence and existence in an actually existing being *entitatively two realities*; or are they at bottom identical and only *one reality in nature*, but with *two*

distinct concepts in the mind? That is the crux of the problem.

The controversy regarding the real or virtual distinction between essence and existence in an actually existing being has held the attention of philosophers, especially among the scholastics, from the Middle Ages to the present day. Men of great caliber, celebrated for the depth and acumen of their insight into philosophic matters, have sought with great eagerness to find a solution for this vexing question; but no one has been able to bring forth arguments which would definitely settle the problems to the satisfaction of all.

There is a very great difficulty in the subject matter itself, since it revolves around two of the most fundamental concepts of the human mind — essence and existence. These two concepts lie so close to the borderland of ‘possible’ and ‘actual’ existence, and the line of demarcation separating them is so fine, that the unhappy controversialist may unwittingly lapse into a begging of the question. In fact, authors have frequently charged each other with this illogical procedure; the recriminations are mutual.

The philosophers of the *Thomistic School* defend the real distinction between essence and existence; it is a cardinal doctrine of their system. A number of scholastics, though not Thomists, follow them in this. Others follow *Suarez* and defend a virtual distinction between essence and existence. There are great authorities in either camp. To do justice to both sides would require extensive quotations, and it is doubtful whether the beginner in philosophy would derive much benefit from these conflicting views. It must therefore suffice here to merely mention the problem.⁴

SUMMARY OF CHAPTER X

Essence and *existence* are a main division of 'being in general.'

1. *Essence*. It is that in virtue of which a being is just what it is. The definition of a being according to its proximate genus and specific difference gives its essence. It is the ultimate principle in a thing from which it derives whatever it possesses in the line of 'being' in any form. It is also called 'nature,' 'quiddity,' 'substance.'

2. *Classification of Essence*. Essence is either physical or metaphysical. *Physical* essence is an essence as it exists concretely in nature, independent of the mind's thinking. It is simple,' if it is constituted by a single substantial principle; it is 'composite,' if it consists of two or more substantial part-principles which together constitute one complete nature. *Metaphysical* essence is the sum of the various grades of being which constitute a thing in the abstract concepts of the mind. These 'grades of being' in a concrete nature are in reality identical and separable only in thought.

3. *Properties of Metaphysical Essences*. Essences, taken metaphysically, are immutable, indivisible, necessary, and eternal. This does not apply to physical essences in their actual existence. Only God's existence has these properties in the actual order.

4. *Existence*. The term does not admit of a strict definition, because existence is a primary reality and concept. It is opposed to mere 'possibility.' It can be

described as that state of a being in virtue of which it is present as an actuality, and not merely as a possibility, distinct from the mind and, if it be a produced thing, distinct from its producing causes.

5. *Problem of Essence and Existence.* The problem is this: Is the distinction between the essence and existence in an actually existing object a real or only a *virtual* distinction? Objects are 'really' distinct, when they are distinct from each other in entity and in concept; they are 'virtually' distinct, when they are distinct from each other in concept, but not in entity. Hence: Are essence and existence in an actually existing being *entitatively two realities*; or are they at bottom identical and *only one reality in nature*, but with *two distinct concepts* in the mind?

PART II

THE TRANSCENDENTAL ATTRIBUTES OF BEING

Chapter 11

BEING AND ONENESS

THE TRANSCENDENTAL ATTRIBUTES OF BEING ARE OFTEN styled 'properties.' In the strict sense of the term, a 'property' is some attribute which is not a direct part of an essence itself, but which flows necessarily from an essence integrally constituted. As such, it must be a positive entity, different from the essence itself. Applying this to the concept of 'being in general,' it is evident that, in the strict sense, there can be no such properties of 'being in general'; because a property that would be different from 'being' would have to be a non-being, and a non-being cannot be an attribute of anything. An attribute that flows necessarily from being must itself be a 'being' and therefore must already be contained in the concept of 'being in general.' However, in a wider use of the word we speak of the properties of being. We call them 'properties,' because they resemble the properties taken in the strict acceptation of the term. Bearing this in mind, *the transcendental properties or attributes of being in general are defined as certain supreme modes or attributes necessarily connected with every being, which are different phases of the same fundamental being, but are not explicitly contained in its*

concept as such. They are called 'transcendental' in as much as they are not confined to any particular category or classification of being, but are found in all, affecting each and every conceivable being: they 'transcend,' or 'go beyond and over,' all categories.

There are six transcendental concepts: *being, thing, something, true, good* (*ens, res, aliquid, unum, verum, bonum*). But of these 'being,' 'thing (reality),' and 'something' are Synonymous; there is no real difference of meaning between them, since all merely signify the opposite of nonentity. A glance at 'one,' 'true,' and 'good,' however, shows that these mean something different in their comprehension, when compared to each other, even though they are identical with the more fundamental concept of 'being.' These, then, *oneness, truth, and goodness*, are the transcendental properties or attributes of being.

In the previous chapters our investigation has considered 'being' only in its concept and in its primary determinations. We must now consider it more in its *relations*. If we consider a being in relation to its constitution, it is 'one.' If we consider it in its relation to another, it may be taken in relation to a knowing intellect, and this adds to it the mode of being 'true'; or it may be taken in relation to an appetitive power, and this adds to it the mode of being 'good.' These three transcendental properties or attributes will be investigated in this order.

THE CONCEPT OF UNITY

When is a being 'one'? Oneness or unity necessarily implies the idea of indivision within a being's own reality. Hence, a being is said to be 'one' when it is *undivided in itself*. This is the most fundamental idea underlying the concept of 'one' and 'unity.' There is no need of comparing a thing with another, in order to speak of its 'oneness'; a thing would be one even if no other being were in existence or possible. God, for example, existed from eternity; He, therefore, had oneness or unity in His own being, irrespective of the fact that He existed alone and no creatural beings co-existed from eternity with Him.

Usually, however, philosophers add another element to this definition, namely, that a being be *divided from other things*. It will readily be observed, though, that this latter is secondary and flows from the first: because a thing is undivided in itself, it will also be divided from all others. Since a thing, according to the Principle of Identity, is what it is, it must primarily be undivided in itself; then, since the thing, according to the Principle of Contradiction, cannot simultaneously be both itself and not itself, it must secondarily be divided from every other. From this it follows that a 'part' of a thing cannot be considered, with respect to some other part of that thing, as being truly one, because it is not actually divided from the other part; a part is united with the other part or parts, to form the unity or oneness of the whole: the whole is one, not the part. On the other hand, a 'compound' would truly be one, because the component parts are not actually divided: the whole has indivision in itself, notwithstanding its composition, and as such it possesses unity or oneness.

Viewed in this light, every being is one, and oneness is a transcendental property of being. *Transcendental unity* can, therefore, be defined as *that mode or attribute of a being in virtue of which a being is undivided in itself (and divided from every other being)*.

From this transcendental unity or oneness we must distinguish *predicamental unity* or oneness. We speak here of the unit or units of numbers. It is called 'predicamental,' because number belongs to the predicament or category of 'quantity.' Predicamental unity or oneness is the same as *mathematical* or *numerical* unity, or oneness, and it is defined as a unit considered as a standard for measuring mathematical or numerical quantity. In the metric system the millimeter, centimeter, meter, kilometer, etc., are mathematical units; in the English system we have the inch, the yard, the rod, the mile. Thus, too, the gram, the liter, the pint, the gallon, the ounce, the pound, the ton, etc., are all mathematical units of measurement. Such units differ with different peoples and with different scientific requirements.

CLASSIFICATION OF UNITY

Beings are said to be 'one,' either because there is unity in them as things, independent of the thinking mind which contemplates them (*real* unity), or because the mind conceives them as possessing unity as a *class*, although in nature they are not actually one (*logical* unity).

Real Unity. Real unity is the *indivision of a thing in its* entity, independent of our mode of thinking. Such a thing

would be undivided in itself and consequently 'one,' even if there were no mind in existence to contemplate it. Thus each object in the world, as it exists for itself, is one: a man, a dog, a bird, a plant, a stone, a star, a proton, an electron. Real unity may be simple or compound.

Real unity is a *unity of simplicity*, or a thing is said to be simple in its unity, when its indivision is such that the thing does *not consist of any parts* into which it could be divided; such a thing is actually undivided and potentially indivisible. A case in point is the soul of man; it is a spiritual being which does not consist of any parts and as such is one and indivisible. The same is true of the essence of God and of pure spirits.

Real unity is a *unity of composition*, or a thing is said to be composite in its unity, when it is a *whole not actually divided into the real parts of which it consists*. A being of this kind has parts within itself, but these parts are so united that they form a unit, a whole, a totality. Man's body, for instance, is composed of head, trunk, and extremities, and each of these consists of various minor parts; but they are not actually separated from one another, so that they would be mutually independent: they form an organism, and an organism is a whole or unit.

If the parts of a composite whole are substantial parts constituting a single nature, there is a *substantial unity*. Man is a single nature, consisting of body and soul. All brutes and plants are composed of a substantial material principle (matter) and a substantial life-giving principle (soul). According to the hylomorphic theory of Aristotle and the scholastics, even inanimate beings consist of two part-

substances, matter and form. If the parts of a composite whole are united because of something accidental, there is an *accidental unity*. There are three possibilities. Two or more substances may be united in an accidental bond; for example, two horses pulling a wagon, a piece of iron attracted by a magnet, the planets and the sun in the solar system. A substance may be united with accidents; for example, the union between the human body and its weight, energy, heat, color. An accident may be united with another accident; for example, the union between the accident of bodily extension in a stone and its modal accident of shape or Size.

The unity of composition may also be metaphysical, physical, or moral. This unity will be *metaphysical*, if the whole consists of grades of being as metaphysical parts, united through mutual compatibility; for example, the metaphysical parts of man's concrete nature are rationality, animality, vegetancy, materiality, and substantiality. It will be *physical*, if the unity of the parts of a whole is effected through the influence of the physical forces of nature; for example, the unity of electrons and protons forming an atom, of various atoms forming a body. It will be moral, if the unity of the various parts of the whole is the result of free-acting agencies; for example, the unity which exists among human societies, governments, firms, armies, families.

Again, if the unity of composition is brought about by means of an inherent tendency of the forces of nature, the result will be a *natural* unity. For example, body and soul in man; feathers, wings, legs, and the other parts of a bird;

roots, stem, leaves, flowers, and fruit in a watermelon plant; hydrogen and oxygen in the formation of water. But if the parts have no natural tendency to form a whole and do so only because an outside intelligence arranges them into a unit, such a unity is *artificial*. Thus, a house, a cap, a watch, an automobile, a ship, a gun, a desk, a book, etc., are artificial units.

In all these cases there is a 'real' unity, a unity of things as things, independent of the mind contemplating them; they have and retain their unity, even though no mind adverts to them.

Logical Unity. This form of unity is entirely dependent on the activity of the mind, and for that reason it is not found in the things of nature as such. Logical unity is the result of a thought process of man's intellect and is due to its generalizing and classifying tendency. The mind groups a number of things, actually divided and separated in nature, into a class on the basis of some similarity existing among them and in this manner unites them into a *conceptual whole*.

Any point of similarity may be taken by the mind as the basis for such a class-idea. Thus, between a human being in America and another in Africa and a third in China there is no possible real unity; they are really separated and divided. And the same fact applies to all human beings, dead or alive, present or past or future. Nevertheless, they all possess the essential similarity of a common human nature — they are 'rational animals.' The mind grasps this similar element in them all and expresses it in a universal idea, the unified concept 'man.' The concept 'man,'

therefore, is a conceptual whole, of which the individual men are considered by the mind as being logical parts.

In this manner the mind develops its universal ideas or class-ideas as conceptual wholes, of which the subclasses or individuals are the logical parts. All universal ideas possess this character. Scientific classifications fall under this head. Beginning with the individuals, they build up class after class, until they cover the entire field in one supreme, all-embracing class. Hence, logical unity is defined as the *indivision of a universal idea (class) considered as a whole of which the inferiors are the parts*.

CONVERTIBILITY OF BEING AND UNITY

When it is stated that being and unity are convertible, the meaning is: *Every being is one or a unit, and everything that is one or a unit is a being*. A brief consideration of the concepts of 'being' and 'one' will show the truth and necessity of this statement. Every being, of whatever kind and character, is either *simple* or *compound* in its nature. This is clear from the definition of these terms: a thing is 'compound,' when it consists of parts; and it is 'simple,' when it does not consist of parts. These terms are contradictory in meaning, and between contradictories there is no middle; hence, according to the Principle of Excluded Middle, every being must be either simple or compound. Whatever is 'simple' is undivided actually as well as potentially, because it has no parts into which it can be divided; consequently, a simple being is undivided in itself and therefore a unit or one. Whatever is a 'compound'

is a compound only in so far and only so long as its parts are united and are not actually divided, because that is what is understood by the term 'compound'; consequently, a compound being is undivided in itself and therefore a unit or one. From this it is evident that the being of every thing, whether simple or compound, is characterized by *indivision*; in other words, every being is a unit or one.

That everything which is a unit or one is also a being, is evident. To be a 'unit' or 'one' means to have the unity of simplicity or the unity of composition. That, however, presupposes that *some thing* has this unity of simplicity or this unity of composition. The concept of the 'unity of composition necessarily involves the concept of a *reality consisting of parts*, and these parts must be real in the whole; otherwise they would be nothing, and nothing cannot be distinguished into parts. For the same reason the 'unity of simplicity' necessarily implies the concept of a *reality consisting of no parts*; if the simple unit were not a reality (being), it would be nothing, and nothing cannot be a unit of any kind, whether simple or compound. Hence, only a being can be a unit or one. From this it follows that 'being' and 'one' are convertible, because they are identical; every being is a unit, and every unit is a being.

Regarding this question, it is well to remember that we are not speaking of *beings*, but of a *being*. We do not deny the plurality of beings in this world, nor do we assert that all beings together form a single being. It is merely a question whether an *individual being* is a unit *in itself*. Concerning a 'simple' being, the matter is easily solved: since it has no parts, it is naturally undivided in itself, and

therefore a unit or one. It is in connection with a 'compound' being that the question of unity can be raised. It consists of parts. Should a being consisting of parts really be considered as 'one,' as a 'unit'? Do not these parts imply a plurality, so that we should speak of 'beings' rather than of a 'being'? It is obvious that the parts of a compound, if actually separated and divided, no longer form a 'compound' at all; each separated and divided part becomes a being of its own, and thus actual division entails plurality. But if they are not actually separated and divided, they are not actually 'beings' either, since in their mutual union they form a unitary 'being.' Now, it is precisely when they are not actually separated and divided, that they form a 'compound.' Hence, so long as a thing is really a compound, it is not a plurality of beings, but *one single being*.

BEING AND INDIVIDUALITY

The unity of being, considered so far, is the unity proper to *all being*, whether possible or actual, abstract or concrete. A 'man,' for instance, is a unit, whether we consider him merely as a possible being who can exist, or as an actual being who does exist, whether we consider his nature in the abstract as a 'rational animal,' or as a concrete reality in the physical world of things: he is considered in all cases to be a compound being consisting of parts which form a complete and unitary nature. And what is true here of man, is true of every other being mentionable or conceivable.

There is, however, a special kind of transcendental unity which is called the *unity of individuality* or the *unity of an individual*; it is defined as the unity of a being which is *one in itself and non-multipliable*. An individual, therefore, is an existing unit of being, incapable of being multiplied; in other words, an individual is 'one' in such a manner that it cannot be divided, so that each member resulting from the division would be the same as the original undivided individual.

The concept of the 'individual' is thus seen to be in opposition to the concept of the 'universal.' The universal is conceived by the mind as a nature common-to-one-and-many; it is capable of being realized in any number of individuals of that class. As a class-nature it is conceived as a (logical, or conceptual) unit; since, however, it is communicable to many, it is multipliable. The individual nature, on the other hand, is conceived as being one for itself alone, so that it is incommunicable to others; there may be any number of individual natures of a certain type and class (e.g., men), but they are *not the same, identical nature*. The individual nature, as an existing individual, since it is not communicable to many, is thus conceived as non-multipliable.

Is this idea of the 'individual' justified? Why should it be impossible for a being to exist concretely in the physical world as a 'universal'? And why must a being, if it exist, exist only as an '*individual*'? For the following reason:

The universality of a universal idea involves the concept of a nature or essence which applies to a *class* as a whole and to every *member* of that class; it is applicable to one-

and-many. Take the universal idea 'man.' It represents a nature or essence ('rational animal') which applies to the whole class of men taken together, as when we state 'Man is mortal'; here we mean that the whole class of men as a class is mortal. But the universal idea 'man' also represents the same nature or essence as applied to each single member of the class of men, as when we state 'Peter is mortal, Napoleon is mortal, Margaret is mortal'; and here we mean that each man is mortal, taken singly and individually. The universal, therefore, is applicable to one-and-many; it is (conceptually) one, but also many. Hence, if the universal could exist *as a universal*, it would exist as 'one' and as 'many' *simultaneously*. That, however, involves a contradiction. As 'one' it would be a unit; as 'many' it would be a plurality: it would exist as a unit and as a plurality simultaneously — an obvious contradiction. It must exist either as a unit or as a plurality; it cannot be both. But we have just seen that every being is one, and oneness excludes plurality. Every being, therefore, if it exist, must be one and singular, not universal and plural. Consequently, no being can exist as a universal, but *only as an individual*.

THE PRINCIPLE OF ABSOLUTE INDIVIDUATION

Every being which exists must exist as an individual being. As such, the individual nature or essence is not communicable to others, but is absolutely restricted to this one individual, e.g., to Peter or Napoleon or Socrates. Individuality, in a philosophic sense, is therefore that state of an existing being in virtue of which it is one in itself and

non-multipliable. This raises an important question: What is the *principle of individuation* which makes an existing being to be an individual, so that its nature or essence is incommunicable to others and is restricted to this one? We can distinguish between an extrinsic and an intrinsic principle of individuation for a being. The 'extrinsic' principle is the cause which gives an individual being its existence. That, of course, is the efficient cause, either God or creature; and with that we are not concerned here. The 'intrinsic' principle of individuation is the ground or reason (principle) in the being itself which *gives individuality* to the being so that it is one in itself and non-multipliable into many. In other words, what is it in the being itself that makes it to be 'this' particular individual (*haecceitas*, 'thisness')? Since this question refers to the single individual, taken absolutely and without any relation to others, this intrinsic principle is called the *principle of absolute individuation*, i.e., the intrinsic principle which gives the unity of individuality to an existing being.

In order to understand the problem rightly, we must compare the 'individual nature' of a being with its 'specific nature.' The specific nature of a being is the result of the union of its proximate genus and specific difference. For instance, the specific nature of man consists of the proximate genus 'animal' and the specific difference 'rational'; the union of the two constitutes the specific nature (species) of man, for 'man is a 'rational animal.' This specific nature is, of course, alike in all men, because all men possess the nature or essence of a rational animal. From this standpoint alone there would be no difference in

the concept of one man and another. In an existing man, however, this general 'specific human nature' becomes an 'individual human nature,' and this is done through the union of the 'specific nature' with 'individuality'; Napoleon, through his individuality, is not merely a *man*, but *this man Napoleon*. In this manner the general 'specific nature' becomes *individuated* in an existing individual by means of a union between it and 'individuality.'

Hence, the question: What is the principle of absolute individuation which makes an individual to be an individual? Is 'individuality' a reality *really distinct* from the reality of the 'specific nature or essence,' united as physical entities in a *physical union*? In this case, the principle of absolute individuation would be the entity of the 'individuality' as such, and not the nature or essence at all. Or, are the 'specific nature' and the 'individuality' in an existing individual *entitatively identical*, with merely a distinction in thought between them, so that they form a *metaphysical union*? In that case, the (formal) principle of absolute individuation would be the entity of the 'individual nature or essence' itself, and there would be only a virtual distinction between 'individuality' and 'specific nature' in an individual. The latter view is correct, and that will now be demonstrated.

If we maintain a *real distinction* in an existing nature between its 'specific nature' and its 'individuality,' we must maintain that the 'individual nature' results from a physical composition of these two entities, so that the 'specific nature,' when it exists, cannot become individuated (i.e., become an individual nature') except through the reality of

this 'individuality.' But this 'specific nature,' *in itself*, must be either a *universal* or an *individual* nature. If it is universal, then a universal nature would exist as a universal; the 'individuality,' being distinct in its entity from the entity of this 'specific nature,' is merely superadded or united to it and cannot change it. As was shown before, however, a universal nature cannot exist in the physical order of things as a universal. Therefore, the specific nature must come into existence as an 'individual nature.' But if it comes into existence as an 'individual nature' the entity of 'individuality' is entirely superfluous and can no longer make it individual, because it is already an 'individual nature' *in itself* when it comes into existence. Consequently, the 'this-ness' or 'individuality' of an existing nature is not really, but only mentally, distinct from the existing nature itself, and the principle of absolute individuation in an existing individual is the *nature* or *essence* itself. In other words, every specific nature, by the mere fact that it exists, thereby becomes an *individuated* (individual) nature. 'Individuality,' therefore, is not an entity added or united to the nature, but solely a manner of existence for it.

The distinction, then, between the 'specific nature' and the 'individuality' or 'thisness' of an existing individual is a mental or *logical distinction*, i.e., there is no distinction between them as 'things,' but there is a distinction between them in their concepts.' That they are distinct in concept, is obvious, because we define them differently; we certainly do not mean the same thing when we speak of the 'nature' and of the 'individuality' of an individual. The question then arises: Is there a ground or reason or *foundation* in the

individuals for making this distinction in concepts? There is. 'Individuality,' as such, is the same in kind for all existing beings; it is simply conceived as that which makes a specific nature to become individuated in this particular individual. But there is a great variety of specific natures among existing beings (e.g., men, plants, animals, inanimate things, etc.), each of which is individuated in a large number of existing individuals, while a still larger number is merely possible and therefore not actually individuated at all. Here we have the ground, the reason, the *foundation in the things* themselves for our making a mental or logical distinction between the 'nature' and the 'individuality' in them. Now, when there is an identity of thing, but a distinction in concept, with a foundation in the thing for making this distinction, this distinction is not real, nor purely mental, but virtual. In an existing individual, therefore, there is a virtual *distinction* between the nature and its individuality.

The Scotists, followers of Duns Scotus, claim that this distinction is a 'formal distinction on the part of the nature of the thing.' In the next chapter we will discuss this formal distinction, and there it will be shown to be invalid.

THE PRINCIPLE OF RELATIVE INDIVIDUATION

In the foregoing problem an individual nature was considered in and for itself, and the problem consisted in determining the principle of absolute determination for this single individual as such. In the present problem the individuals of a certain species, as they exist in the world of

real beings, are taken in relation to each other, and the problem consists in seeking to determine the principle of individuation in virtue of which it is possible to have a number of *individuals of the same species*. To express the problem in a more concrete manner: What is the principle which individuates a specific nature, for example 'man,' into a number of individual natures or individuals, like Peter, Paul, Napoleon, etc., so that it is possible to have more than one individual of that species? This principle is called the *principle of relative individuation*. A solution of the problem has been attempted along two lines.

St. Thomas Aquinas and in general the scholastics follow the view of Aristotle and consider the principle of relative individuation to be *matter affected by dimensive quantity*. They reason as follows: Since it is a question of the plurality of individuals in the same species, the principle of individuation must be a principle of plurality. Plurality implies division and divisibility. The ground or principle of divisibility will, therefore, also be the ground or principle of plurality. Consequently, the ground or principle of relative individuation must be that ground or principle of divisibility which enables a specific nature to be multiplied into a plurality of individual natures. Now, in the physical order, the ground or principle of divisibility lies in *matter* as affected by dimensive quantity (*materia sub dimensionibus signata*), because matter alone, with its threefold dimensions, is *of itself divisible* in such a manner that a plurality of individuals can arise through its division. When a portion of matter is separated from another, due to a division of its dimensive quantity, a plurality is effected in it

which gives rise to a plurality of individual beings of the same species.

This is observed in *inorganic* beings. A piece of gold can be divided into a number of individuals of the same species of gold by a simple division of its quantity. In organic beings a new individual arises through a variety of processes, but they are all effected through a division of the quantity of matter. Whether the generation of new individuals takes place through fission or budding, by means of spores or seed, it always happens through the division and separation of a portion of matter affected by quantity in its threefold dimensions. Quantified matter, then, is the principle of relative individuation.¹

Such is the solution of St. Thomas and his followers. The theory explains the individuality and plurality of *corporeal* beings, as we know them to exist in this physical world. It also explains the plurality of individual human *souls*. Souls, though spiritual in nature, are essentially ordered toward union with a certain amount of quantified matter, so as to form with it a body; man is naturally a compound of soul and matter, and the soul is not a pure spirit. This ordination toward union with matter, since it is a natural exigency of the soul, can never be lost. Hence, even after death a disembodied soul will retain its separate individuality with respect to other souls. However, it also follows as a logical consequence of this theory that *pure spirits* cannot be multiplied as individuals in the same species. They do not consist of matter, nor have they a natural ordination toward union with matter. For this reason a plurality of individual pure spirits, belonging to the same species, is impossible,

because 'quantified matter' is the principle of relative individuation. The result of this theory would be that each single pure spirit represents a distinct species. Of course, the human mind, in its condition of embodiment on earth, has no way of either directly proving or disproving this contention. In virtue of its own observation it cannot know whether or not pure spirits are represented by a number of individuals within the same species; in fact, it is questionable whether the human mind, with the natural light of reason alone, can prove even the existence of pure spirits. But there certainly seems to be no contradiction in the *idea* of a plurality of individual pure spirits within the same species. To deny such a plurality of individuals, then, as this theory does, would rather seem to be a weakness of this theory which places the principle of relative individuation in quantified matter.

For this reason, *Suarez*,² and others with him, offer a different solution of the problem. According to them, the principle of relative individuation lies in the *contingency* and *finiteness* of creatural beings. God, because He is infinitely perfect, subsistent in virtue of His own essence, possesses the unity not only of individuality, but also of unicity: there can be but one God. With creatural beings the situation is radically different; since they are contingent and finite both in essence and existence, they are multipliable into any number of individuals of the same species. Here is the reason.

The possibility of any creatural being to acquire existence is derived from the *imitability* of God's infinite essence. Because God is imitable by created essences, His

omnipotence can create them. That, as was shown before, is the ultimate foundation of their possibility. Since, however, His essence is infinitely perfect, it is infinitely imitable, both *intensively* and *extensively*; if this were not so, it would not be infinitely perfect in itself. That His imitability be infinite 'intensively,' means that His essence can be imitated by all kinds or *species* of being without number; and that it be infinite 'extensively,' means that each kind or species of being can be represented by *individuals* without number. The actual number of such imitations will, of course, never exhaust the possibility of the imitability of God's essence, for the very reason that God's essence is actually infinite as an existing reality. Consequently, no creatural being can ever be so perfect in essence or existence that other individuals of the same species would not be possible. As a result of this, any number of individuals of the same species can receive existence through the omnipotence of God. And this is true both of pure spirits and of corporeal beings; there is no difference between them in this respect, because both classes are contingent and finite. To say that the various species of pure spirits could not be represented by a number of individuals, would seem to be tantamount to placing a limitation on the imitability, and thereby also on the perfection, of God. The principle of relative individuation, therefore, lies in the contingency and finiteness of creatural beings.

These are some of the problems which arise from the transcendental attribute of being as 'one.' They may not have much practical value, but they give us a better

understanding of the ultimate metaphysical constitution of things, and that is always something worth knowing.

SUMMARY OF CHAPTER XI

Transcendental properties or attributes of being in general are the supreme modes or attributes necessarily connected with every being, which are different phases of the same fundamental being, but are not explicitly contained in its concept as such. Such are the attributes of *one, true, and good*.

1. *The Concept of Unity.* Something is 'one' which is *undivided in itself* and divided from every other being. This transcendental oneness or unity must be distinguished from 'predicamental unity,' which is the unity of a quantitative being considered as a standard for measuring quantity.

2. *Classification of Unity.* Unity will be either real or logical.

Real unity is the indivision of a thing in its entity, independent of our mode of thinking. It is a unity of *simplicity*, when the indivision is such that the thing does not consist of any parts into which it could be divided. It is a unity of *composition*, when the thing is a whole not actually divided into the real parts of which it consists. If the compound (whole) consists of substantial parts, it is a 'substantial' unity; if the parts are united together because of something accidental, it is an 'accidental' unity. The unity of composition may also be metaphysical, physical, or moral, depending upon the fact whether the uniting bond is metaphysical, physical, or moral; it may also be a natural or artificial unity.

Logical unity is the indivision of a *universal idea* (class) considered as a conceptual whole of which the inferiors are the parts. In this sort of unity the things are actually divided from each other, independent of the mind, and form no real unity; but the mind unites them into a class-idea or conceptual whole, due to some common element in which they are similar.

3. *Convertibility of Being and Unity*. This means that every 'being' is 'one,' and everything that is 'one' is a 'being.' Every being has unity, either of simplicity or of composition. Everything that is 'one,' is a 'being.' If it were no being, it would be 'nothing' and 'nothing' can have no unity either of simplicity or of composition.

4. *Being and Individuality*. Individuality is a kind of transcendental unity, in virtue of which a being is one in itself and non-multipliable. The individual is opposed to the universal or class. The 'universal' represents a nature common-to-one-and-many; it applies to the class as a whole and to every member of that class. If a universal could exist as a universal, it would exist as 'one' and as 'many' simultaneously; but that is impossible: consequently, a being can *only exist as an individual*, not as a universal.

5. *The Principle of Absolute Individuation*. By this is meant the intrinsic principle which gives the unity of individuality to an existing being. There is only a *virtual* distinction between the 'specific nature' and the 'individuality' in an existing being, because the 'specific nature' cannot exist as a universal, but only as an individual nature.

6. *The Principle of Relative Individuation*. The problem is: What is the principle of individuation in virtue of which it is possible to have a number of individuals of the same species? *St. Thomas Aquinas* and others consider this principle to be matter affected by dimensive quantity. *Suarez* and others consider it to lie in the contingency and finiteness of creatural beings.

Chapter 12

IDENTITY AND DISTINCTION

UNITY OR ONENESS IS A TRANSCENDENTAL ATTRIBUTE OF BEING. Every being is one or a unit, and everything that is one or a unit is a being: 'being' and 'one' are convertible. As things they are identical, but as concepts there is a distinction between them.

The terms 'identity' and 'distinction' play an important role in philosophy. The terms, however, have a variety of meanings, and their indiscriminate use frequently gives rise to confusion of thought. It will be necessary, therefore, to give a somewhat detailed exposition of both terms. In its fundamental meaning, *identity* is a *sameness between concepts or things*; *distinction* is the *absence of sameness between concepts or things*.

'Things' are real beings, and as such have an entity independent of the mind's thinking process. 'Concepts,' on the other hand, are the result of the mind's activity, and as such have only a mental or logical entity. We, therefore, speak of a real or logical identity, and also of a real or logical distinction.

REAL IDENTITY

Real identity is the sameness (oneness) of things in themselves. A distinction between them may be made in the concepts of the mind. For instance, we speak of man as a 'being' and as a 'substance.' Mentally we make a distinction between these two; but as things they are identical: man's being is his substance, and his substance is his being. Hence, there is a real identity between being and substance in man, notwithstanding the distinction between their concepts made by the mind.

A real identity is a metaphysical identity, when a being is one with itself so that it *can absolutely not change in any manner*. Since God is infinitely perfect, He possesses all being and perfection without regard to past, present, or future. If He could gain or lose any degree of being or perfection, He would not be infinitely perfect. He must, therefore, possess His infinite perfection from all eternity and keep it through all eternity; and this means, that He can absolutely not change in any manner. God, then, is metaphysically identical with Himself, beyond and above all change.

A real identity is a *physical* identity, when a being is one with itself so that it *does not change in its essential reality*, although it can change in its accidental realities. Thus, the human soul, as will be shown in psychology, is spiritual in nature. It has the unity of simplicity, being devoid of any substantial parts into which it could be divided. A simple being of this kind can be annihilated, but it cannot undergo any change in its essence. It can, however, undergo an

alteration in its accidental realities. Every thought, for instance, involves the transition from the potentiality of thinking to the actuality of thinking, and that is an accidental change. Such a being, therefore, is physically identical in its essence.

A real identity is a moral identity, when a being is one with itself so that the *change which takes place in its essential being is successive and gradual*; although it undergoes a change, this change is such that, in the common estimation of men, it still remains the same. Due to this change, none of the original parts may possibly be left after a lapse of time; however, these original parts have been supplanted by new material, so that the fundamental structure or organization has remained intact throughout the entire process of change. A case in point is the human body. The vital functions are continually tearing down old material and replacing it with new material; but this change is so gradual and imperceptible that the general structure of the body remains fundamentally the same to the end of life. This is true of every organism, as long as it lives. So, too, a society or government or nation may retain its moral identity for a hundred or a thousand years and longer. After a few generations not a single original member will be living; nevertheless, the society or government or nation will continue preserve its moral identity, because the organization has not been dissolved, but has retained its structure intact through the successive and gradual assimilation of new members.

LOGICAL IDENTITY

Logical identity is the *sameness (oneness) of things based upon the same concept of the mind*. Logically identical things are not one in reality; they are a plurality of things, each of which is not entitatively the same as the other. They agree, however, in some similar element, and on account of this similarity the mind groups them into one concept and considers them *identical in this respect*. Such things, therefore, are really distinct, but conceptually the same. The similarity existing between such things will lie either in their essence or in their accidents; correspondingly, logical identity will be either in essential or an accidental identity.

An *essential* logical identity is the logical identity of things based upon the *similarity of their essence*. Peter, Paul, Napoleon, and all human beings agree in this that they possess a similar human essence; as 'men,' therefore, they are logically identical in their essence. Men, brutes, plants, and inanimate things are essentially similar to each other in so far as they are 'corporeal'; they are, therefore, conceived by the mind as possessing an essential logical identity. If the essence expressed in the concept represents the genus, so that the things are similar in their 'generic essence,' we have a *generic* identity; thus, men and lions are generically identical, because they possess a similar generic essence, namely 'animality.' If the essence, in which they are similar, is the 'specific essence' or species, we have a *specific* identity; for example, Peter and Paul and Napoleon are specifically identical, since they are alike in their species, namely 'humanity.'

An *accidental* logical identity is the logical identity of things based upon the *similarity of their accidents*. Any accident may be taken as the point of comparison between things, and a conceptual identity will thereby be established between them. If the accident, in which things are similar, is a quality, it will be a *qualitative* logical identity. Thus, snow, milk, sugar, and clouds are qualitatively identical so far as 'white color' is concerned. A toothache, rheumatism, and neuritis, from the standpoint of 'pain,' are qualitatively identical. If this accidental identity is based on similarity in quantity, it will be a *quantitative* logical identity. For instance, two men, each weighing one hundred and fifty pounds, or each having a height of five feet and ten inches, are quantitatively identical.

REAL DISTINCTION

Identity is the sameness between concepts or things; distinction is the absence of identity or sameness between concepts or things. And just as there is a real and logical identity, so there is also a real and a logical distinction.

Real distinction is the absence of sameness between *things different in their reality*, independent of the mind's consideration. The entity of the one is not the entity of the other, even though they be parts of the same totality. A tree and a house are really distinct, because the reality of the tree is different from the reality of the house. The various leaves and branches of a tree are really distinct among themselves, although they are parts of the same tree; and the foundation stones, the bricks, the boards, and the

plaster are really distinct with respect to each other, even though they belong to the house as a whole. A real distinction may be either a 'major' or a minor real distinction.

A distinction is a *major* real distinction, when there is an absence of identity between thing and thing to such an extent that they are distinct from each other as *entities*. Hence, if two or more beings are actually separate, and each exists for itself. they are really distinct beings, with a major real distinction between them; for example, stars, plants, animals, men, metals, buildings, and in general all the individual objects we perceive in the physical world. Again, entities may actually be united in a single being, but so long as they could exist separately, if they were actually divided, they are really distinct among themselves with a major real distinction; for example, the distinction between two substantial or integral parts of the same substance, like apple and apple tree, the branch and its leaves, the right and left side of a stone, the paws and legs of an animal, body and soul in man. So, too, the distinction between a substance and its accidents is a major distinction, if the accident confers a positive entity upon the substance in which it inheres; for example, a corporeal substance and its quantity. Finally, a major distinction exists between accidents, when the entity of each is of a different order; for example, quantity and quality, thinking and willing, warmth and seeing.

A distinction is a *minor* real distinction, when there is an absence of identity between a *thing and its mode*. A 'mode' is the actual determination of a being which is indifferent

toward this or that determination, but without the mode adding a new entity to it through the modification. It is of such nature that it confers no new entity upon its subject and is distinguished from 'nothing' through and in its subject only; the subject can exist without a particular mode, but the mode cannot exist outside the subject which it modifies. A 'mode' is more than a mere logical being (*ens rationis*), and as such is more than a fabrication of the mind; it really affects the subject, independent of the mind, by determining the indifferent subject to a definite manner of being or existence.

Perhaps an example or two will clarify our concept of a 'mode.' Place a coin on the table, with its face downward; and then reverse it, with its face upward. There is a real difference of position here, and it really affects the coin, independent of all thought; but the different positions add no new entity to the coin as such. You cannot separate this position of the coin from the coin itself; the coin is indifferent to various positions, but each position gives a definite 'mode' to the coin. Or, take a lump of modeling clay and shape it, first into a sphere, and then into a cube. This shaping merely shifts the outer limits or boundaries of the quantity of the clay, without adding any new entity to the quantity itself; the shape (sphere, cube, cone, etc.) is nothing but a 'mode' of the quantity (extension) of a body, in as much as it gives determination to this quantity which, of itself, is indifferent to various shapes. These shapes, though, are distinct, because they differ among themselves and actually modify the subject. Again, take curved motion and straight motion. The curvedness and straightness of the

motion are not entitatively different from the motion itself; but they are 'modes' of motion, which imply a difference of direction in the motion, giving this motion a definite determination. Such modes, therefore, are distinct from their subjects with a *minor* real distinction.

Besides a major and minor real distinction we also have an adequate and an inadequate real distinction. A real distinction will be *adequate*, when things are distinct *in their total being*. Such is the distinction between George Washington and Napoleon, between a book and a table, between one piece of gold and another, between two apples or pears or oranges, etc. A real distinction will be *inadequate*, when the things are distinct as *part and whole*. The whole thing is always really distinct from any one of its constituent parts, otherwise the part would be the whole and the whole would be only a part; the whole is the sum of all the parts taken together and cannot be identified with only one of the parts to the exclusion of the others. The whole, however, is *partly identified* with each of its constituent parts; there is, consequently, an inadequate distinction between them. Such is the distinction between a block of ice and its lower (or upper) half, between a dog and its tail, between a plant and its roots, between a house and its roof, between a man and his head, between a pipe and its bowl, etc.

We also speak of a positive and a negative real distinction. It is a *positive* real distinction, if the distinct things are *real (positive) entities* and differ in their entities. For instance, a tree and a stone, a pen and its ink, two books, two elephants, two magazines, two men. It is a

negative real distinction, if there is a *non-entity* either on one side or on both sides of the distinction. On one side: life and death, sight and blindness, health and illness, light and darkness, etc. On both sides: death and blindness, dumbness and deafness, illness and darkness, etc. It may be questioned how it is possible to have a real distinction between non-entities, since they are physically 'nothing.' The fact is that such non-entities are the absence or privation of *definite beings*; since these definite beings are really distinct from each other, their opposites are also really distinct from each other.

Signs of Real Distinction. Bilateral or unilateral preservation in existence after separation; for example, an apple and the tree on which it is growing, a lump of clay and its 'squareness' of shape. The *procession* of the one from the other as from its real principle; for example, light and the sun, child and parent, flower and plant. *Contrariety of concepts*, so that the concepts imply incompatible elements; for example, matter and spirit, man and brute, substance and accident.

LOGICAL DISTINCTION

Our experience shows us that the things in nature do not form one single reality. They are a plurality, a multitude of beings. They are different entities, and as such are distinct in thought and thing; there is a real distinction between them. It is equally true, however, that we often have different concepts of things that are really one in nature; they differ in thought, but not in the thing. Such a

distinction is called *a logical or mental distinction*, and it is defined as *the absence of sameness between concepts of the same reality*. In making this distinction between concepts of the same thing, there is either a reason in the thing itself for making it, or the reason for making it is only in the mind. Correspondingly we have a 'virtual' or a 'purely mental' distinction.

A *purely mental distinction* (*distinctio rationis ratiocinantis*) is the distinction between different concepts of one and the same reality, *without a foundation in the object itself* for making the distinction. The distinction is due solely to the distinguishing power of the mind itself (*ratio ratiocinans*). The content of the different concepts is identical, the meaning is the same; the difference between them lies merely in the difference of the manner of their representation. There are a few general types of this purely mental distinction.

Such are terms and ideas which are more or less *synonymous* in meaning. Examples of this type are: a ton and two thousand pounds; the sky, the heavens, the firmament, the welkin; the sun and the day star; Christ and the founder of Christianity; six and half a dozen. Each concept in its respective group represents the same reality, but in a somewhat different manner. Another type is that of *definitions* and of the *things defined*. Cases in point are: man and rational animal; plant and non-sentient organism; clock and mechanism for measuring time; intellect and rational faculty of thought; water and compound of two atoms of hydrogen and one atom of oxygen per molecule. The concept expressed as the definition is clearer than that

of the thing defined, but they evidently mean the same thing. Another type is found in certain *transcendental ideas*, namely 'being,' 'thing or reality,' and 'something' (*ens, res, aliquid*). The mind here makes a distinction between these concepts, but they are all really identical in meaning with respect to the object for which they stand. In all these types and instances there is a purely mental distinction between the different concepts of the thing, because there is no foundation or reason or basis in the thing itself for making these distinct concepts of it.

A *virtual distinction* (*distinctia virtualis, distinctio rationis ratiocinatae, distinctio rationis cum fundamento in re*) is the distinction between different concepts of one and the same reality, *with a foundation in the object itself for making the distinction*. Here the distinction is not due solely to the distinguishing power of the mind; the mind is induced to make the distinction because of the nature of the object itself, and the object, as it were, forces the mind to make the distinction (*ratio ratiocinata*). The limited power of the mind is incapable of expressing the whole reality of the object in one adequate concept and for that reason expresses it in a number of concepts, each of which expresses a phase of the one reality; the concepts are, therefore, not identical in meaning, when compared to one another, but they all refer to the same reality taken as it is in itself. This will become clearer when we consider the two kinds of virtual distinction, based upon the two kinds of 'foundations' which are possible: they are the virtual distinctions with a perfect and with an imperfect foundation in the thing.

The virtual distinction with a *perfect foundation* in the thing is the virtual distinction in which the concepts are so distinct in comparison to each other, although they apply to the same reality, that they are *objectively different in content*. They are so distinct that the concepts are not mutually inclusive, but each has a definition different from that of the other. The concept of man's essence is made up of these five distinct and objectively different concepts: 'rationality, animality, life, body, substance.' These concepts, however, as has been mentioned before, do not represent five distinct and entitatively different *realities* in man. If they did, a preposterous result would ensue for man. His 'substance' would be really distinct from his 'corporality'; these two would be really distinct from his organism or 'life'; these three would be really distinct from his 'animality'; and these four would be really distinct from his 'rationality.' Man would then be a five-part being. That, however, is not the case: man is one being, a *single substance*; and this substance is a single reality which is bodily, living, sentient, and rational at the same time. Man is not a 'substance' with one part of his being, a 'body' with another, an 'organisms with another, an 'animal' with another, and finally a 'rational being' with another: he is all these things at once and as one.

So far we have seen that we have five objectively different concepts for one and the same reality. Is this a purely arbitrary distinction on the part of the mind, without a foundation in the nature of man himself? On the contrary, man's *nature* contains the *foundation* or reason or basis because of which the mind makes these objectively different

concepts of the one reality of man. These concepts represent *grades of being* which, though really only a single essence in man, are rightly distinguished from one another, because they can be, and actually are, *separately realized in other beings*. Pure spirits, for instance, are 'substances,' but not bodily substances; here we see one grade of being, as found in man, separately realized. Chemical elements and compounds are substances, but they are '*bodily substances*'; here we see two grades of being of man separately realized. Plants are bodily substances, but they are '*living, bodily substances*'; here we see three of man's grades of being separately realized. Brutes are living bodily substances, but they are '*sentient, living, bodily substances*'; here we see four of the five grades of being present in man separately realized. Man himself is a sentient, living, bodily substance, but he is a '*rational, sentient, living, bodily substance*,' with an additional essential element of his own, namely 'rationality.' Each grade of being thus gives rise to a different type, when added to the other or others; in man, however, we find all five united into a single substantial reality. Here, in the very nature of man, we have the reason or basis or *foundation* for making a distinction of five different concepts concerning his one essence.

To sum up: When the mind forms objectively different concepts of the same reality, and these concepts have as their foundation the fact that they can be separately realized in nature in different kinds of being (though in this individual kind of being under consideration they stand for

one reality only), then we have a *virtual* distinction with a *perfect foundation* in the thing.

Man's essence was chosen as a typical example, because we are fairly familiar with it. But cases of such virtual distinctions are found in all creatural beings, whenever we distinguish between the various *metaphysical grades* of their essence. Virtualists also contend that the distinction between *essence* and existence in an actually existing being is only a virtual, not a real, distinction. A case in point, too, is the distinction which we make between the concepts of the *soul* in man, when we speak of it as a 'vegetant' soul, a 'sentient' soul, and a 'rational' soul. The soul is the life-giving principle in an organism. A plant demands a soul for its vegetant functions; a brute demands a sentient soul for its sentient functions; man's rational operations demand a rational soul. Since man has the triple vital functions of vegetancy, sentiency, and rational thought, we speak of a vegetant and sentient and rational soul in man. There are, however, not three souls in man; he has *one soul* which performs these triple functions. Since, though, we have a foundation or reason in the nature of the soul itself for making a distinction, the distinction we make in man between a vegetant, sentient, and rational soul is a virtual distinction with a perfect foundation.

Besides a virtual distinction with a perfect foundation in the thing we have a *virtual* distinction with an *imperfect foundation* in the thing. It is the virtual distinction in which the different concepts of the one reality are distinct in such a manner that they are not mutually exclusive but rather *include each other implicitly*. It will be manifest that, since

the one contains the other implicitly, they can never be realized separately, because the one cannot be present without the other. The reason, however, why the mind makes a distinction between them lies in the object itself. There is thus a *foundation in the thing*, but is not as adequate a foundation as the one of the virtual distinction with a perfect foundation. Examples will clarify the meaning of this.

Such a distinction exists between the concept of '*being*' and its inferiors. In man, for instance, there is no complete and perfect difference between 'being' and 'substance,' 'being' and 'body,' 'being' and 'life,' 'being' and 'sentiency,' 'being' and 'rationality.' By the concept 'being' we mean anything that is 'not nothing.' But that includes absolutely everything conceivable; consequently, 'being' includes within itself implicitly also substance, body, life, sentiency, and rationality. Similarly, these various concepts include implicitly the concept of 'being' within themselves, because their reality is a form of being. Hence, the distinction between 'being' and any particular kind of being is based upon an imperfect foundation.

We have another instance of this sort of distinction in the *attributes of God*. God's wisdom, mercy, power, intelligence, etc., are virtually distinct with an imperfect foundation. This is due to the *infinite* perfection of God's nature. In themselves the concepts of wisdom, mercy, power, intelligence, etc., are objectively different and can be separately realized: this is seen in creatures. When, however, it is a question of *infinitely' perfect attributes*, they cannot be separately realized. If infinite wisdom and

infinite power could be separately realized, it would mean that each would not include the other; but by that very fact neither of them would really be 'infinite,' because each would lack the perfection contained in the other. Each attribute of God is really identical with the other and with His essence; and a plurality of infinite perfections, separately realized and existing, is a contradiction in thought. Where, then, is the *objective foundation* for making the distinction between them? Not in God Himself directly, but in the creatures, in as much as we perceive wisdom and mercy and power and intelligence appearing separately in creatural beings. Hence, the objective foundation for making the distinction between these attributes in God is *imperfect*.

Another instance worthy of special attention is the distinction between *being, one, true, and good*. We have seen that every 'being' is 'one,' and that everything that is 'one' is a 'being.' The same will be shown later regarding truth and goodness. All these concepts are convertible. These concepts are distinct, and the distinction between them is not purely mental; but each contains the other implicitly, and they cannot be separately realized. Hence, the distinction between these concepts is a virtual distinction with an imperfect foundation in the thing.

From the above exposition it will be clear why these distinctions are styled '*virtual*.' The concepts are distinct and different. Since, however, they apply to a single reality, they do not stand for distinct physical parts in this reality, which together make a physical composition. Rather, they stand for *metaphysical parts* which are united together in a

metaphysical composition. These parts are present in the thing *not actually* as parts, but only potentially or *virtually*.

THE SCOTISTIC FORMAL DISTINCTION

John Duns Scotus (1266 [or 1274]—1308) is famous for his deep and sharp thinking. One of his noted doctrines is his *formal distinction, actual on the part of the thing* (*distinctio formalis actualis ex natura rei*). Scotus did not deny any of the distinctions mentioned above; he admitted a real distinction, a virtual distinction, and also a purely mental distinction. But he contended that there is still another distinction which must be placed between a real distinction and a virtual distinction; it is not as great as a real distinction, and it is greater than a virtual distinction which has only a ‘foundation’ in the thing.

Scotists claim that there are not only ‘entities’ present in an object, between which there is a distinction of thing and thing (real distinction), but an object also has certain *realities* or *formalities* which are actually, though not really, distinct from each other. A ‘real’ distinction would thus be a distinction between things, and a ‘formal’ distinction would be one between *formalities*. By a ‘formality’ (*ratio formalis*) Scotus understood a positive thought-content or reality, objectively different from another, which in the individual under consideration is so essential to it that the thing cannot exist without it, nor can this thought-content exist except in this individual. An illustration will help to understand the Scotists’ meaning.

Man is a rational animal. 'Rationality' and 'animality' are present in man's nature. These are two completely different concepts or *formalities*: 'animality' is one, and 'rationality' is another formality. Although both thought-contents represent one thing in man, they are two entirely different 'formalities' or, in other words, diverse concepts. This, they say, will be clear from a simple comparison. The 'animality' of man is the same as the 'animality' of the lion or of any other animal. But the 'animality' of a lion is *actually* distinguished from 'rationality.' Consequently, the 'animality' of *man* must also be *actually* (though not really, as between thing and thing) distinguished from his 'rationality.' Since, therefore, 'animality' and 'rationality' are not distinct as different entities and things, they are not really distinct in man; but they are *actually distinct* in man as *formalities*, independent of any mind. Hence, there exists between 'animality' and 'rationality' in man, due to his nature and independent of any mind, a formal distinction, actual on the part of the thing.

We must *reject* this Scotistic formal distinction as invalid, because it is impossible for a distinction to be actual without being also real. If something is actually distinct from another, *independent of the mind*, it must be *ontologically* distinct from this other, i.e., distinct in its being or entity. The Scotists themselves admit that a formal distinction is 'actual on the part of the thing (*ex natura rei*),' and that implies that the distinction is not logical, but ontological. Since every distinction involves plurality, an actual (or formal) distinction involves an ontological plurality, i.e., a plurality in being or entity. Hence, if these

‘formalities’ bring in an actual distinction in the nature of the object, independent of the mind, they thereby also bring in an ontological plurality, and this can only be a *plurality of entity*. But a plurality of entity means not one thing, but ‘different things’; and between one thing and another thing, between entity and another entity, there is a *real* distinction. Therefore, if the formal distinction is ‘actual on the part of the thing,’ it is a ‘real’ distinction and no longer merely ‘formal.’ In other words, the whole conception of the ‘formal distinction’ is invalid, because it amounts to a ‘real distinction.’ And since it is clear that ‘animality’ and ‘rationality’ (and all other metaphysical grades of being) are not really distinct, but form a single reality in man, the fact of the separate realization of ‘animality’ in the brute (e.g., in the lion) is merely the *foundation* for a difference of concepts on the part of the thinking mind. But this means a ‘virtual’ distinction with a foundation in the thing. It is obvious, then, that there is no special distinction, formal or other, midway between a real and a virtual distinction.

In the view of some modern Scotistic scholars, the interpretation of the Scotistic formal distinction, as given above, is based upon a misunderstanding of the true meaning of Duns Scotus. According to their opinion the formal distinction coincides essentially with the virtual distinction with a foundation in the thing. The former stresses the objective factors in the thing which give rise to the mental distinction, while the latter emphasizes the subjective factors of the mind which expresses the single (but equivalently multiple) reality with two or more distinct concepts. “Because of the well-known difference in mental

temperament St. Thomas, the Intellectualist, saw and felt the distinction primarily as a mental distinction, and so defined it as a *distinctia rationis*, admitting, however, that it has an antecedent and independent foundation in reality, whereas Scotus, with his more realistic temperament, was more powerfully impressed by the objective factor and so emphasized the fact that it is a *distinctio a parte rei*; adding, however, that it was not simply a real distinction between thing and thing, but only a distinction between a *res* and its *realities* that is, between a thing and its intrinsic modes (*formalitates*), and consequently admitting that it is a mental distinction in so far as we have two mental concepts representing one thing of nature."¹

If this view can be upheld, much of the opposition to the Scotistic distinction must be dropped. Most scholars, however, are convinced that Scotus maintained a 'formal distinction' which occupies a position midway between a 'real' and a 'virtual' distinction; such a distinction, as shown, must be rejected.

SUMMARY OF CHAPTER XII

Identity is the *sameness (oneness)* among two or more concepts or things. *Distinction* is the *absence of sameness (oneness)* among two or more concepts or things.

1. *Real Identity*. It is the *sameness (oneness) of things in themselves*, independent of the mind. It is a 'metaphysical' identity, when a thing is one with itself so that it can absolutely not change in any manner. It is a 'physical' identity, when it is one with itself so that it does not change in its essential reality. It is a 'moral' identity, when it is one with itself so that the change which takes place in its essential being is successive and gradual.

2. *Logical Identity*. It is the *sameness (oneness) of things based upon the same concept of the mind*. This is an 'essential' identity, if it is based upon a similarity of essence. It is an 'accidental' identity, if it is based upon a similarity of accidents.

3. *Real Distinction*. It is the *absence of sameness between things different in their reality*, independent of the mind. This is a 'major' real distinction, when the absence of identity between things is such that they are distinct from each other as entities. It is a 'minor' real distinction, when it is the absence of identity between a thing and its mode. A real distinction is an 'adequate' real distinction, when things are distinct in their total being. It is an 'inadequate' real distinction, when the things are distinct as part and whole. A real distinction is a 'positive' distinction, when the distinct things are real (positive) entities. It is a 'negative'

distinction, when there is a nonentity either on one side or on both sides of the distinction.

4. *Logical Distinction*. It is the *absence of sameness between concepts of the same reality*. A 'purely mental' distinction is the distinction between different concepts of one and the same reality, without a foundation in the object itself for making the distinction.

A '*virtual*' distinction is the distinction between different concepts of the same reality, with a foundation in the object itself for making the distinction. The virtual distinction will have a 'perfect' foundation in the object, when these concepts are objectively different in content. The virtual distinction will have an 'imperfect' foundation in the object, when these concepts include each other implicitly.

5. *The Scotistic Formal Distinction*. It is a distinction, maintained by Scotus and his followers, that has a position midway between a real and a virtual distinction: it is *actual*, though not *real*. By 'formality' in a thing is understood a positive thought-content or reality, objectively different from another, which in the individual under consideration is so essential to it that the thing cannot exist without it, nor can this thought-content exist except in this individual. Such 'formalities' are the metaphysical grades of being, like 'rationality' and 'animality' in man.

This formal distinction is *invalid*, because an *actual* distinction is a real distinction. Whatever is actually distinct from another, independent of the mind, must be *ontologically* distinct, i.e., distinct in its being and entity. Distinction involves plurality, and actual distinction must, therefore, involve an ontological plurality, i.e., a plurality in

being and entity. That, however, means a 'real' distinction. Consequently, the Scotistic formal distinction is a *real* distinction.

Chapter 13

BEING AND TRUTH

EVERY BEING, CONSIDERED IN ITS INNER CONSTITUTION, IS undivided and one. Unity or oneness is a transcendental attribute of being as such. Every being possesses this attribute absolutely and essentially; it is a unit in itself, even though no other being existed. As a matter of fact, however, no being is a completely isolated reality, because there is a vast multitude of beings in existence. This induces numerous relations between beings and beings.

Among these various relations, two are *transcendental* for every being: *truth* and *goodness*. Every being in its very nature has a relation to intellect and will, in virtue of which it is 'true' and 'good.' The will can only strive for something in so far as a thing is apprehended by the intellect as good; consequently, a being has a relation to the intellect before it has a relation to the will. Now, the relation of a being to the intellect is the *relation of truth*, because it is the purpose of the intellect to acquire truth. The truth of a being is, therefore, logically prior to its goodness. Hence, we must treat of the transcendental attribute of truth in a being before we treat of its goodness.

CONCEPT OF TRUTH

Truth always has a reference to the mind or intellect. Truth is an attribute of something that is *known*, and it is the mind or intellect that knows. Naturally, being what we are, truth exists *for us* primarily in our own intellect, and we come to understand the nature of truth by observing our own mental operations.

By 'truth' we ordinarily mean *true knowledge*, and by 'true knowledge' we mean *true judgments*. Ideas are more in the nature of a prerequisite for knowledge than real knowledge itself; they must be united in a judgment in order to be knowledge, and then this judgment is either true or false. To have the ideas 'weather,' 'warm,' 'cold,' and 'freezing' in the mind, is not a complete form of knowledge, nor can we say that such ideas are true or false. But if we make a pronouncement about the weather and assert that 'The weather is warm,' we have a mental judgment, and this judgment either agrees with the actual conditions of the weather or it does not; if the weather actually is warm, our judgment is 'true,' and if the weather is not warm, our judgment is 'false.' Correspondingly, we have 'truth' or 'falsity (error),' and both reside in the *judgment of the intellect* in so far as the intellect agrees or disagrees with the thing about which it judges. Here, then, truth is seen to be an attribute of our knowledge and judgment.

Truth, however, can be taken in a different sense. We also speak of the *truth of things*. It is a matter of everyday experience to hear people apply truth to things, but they may use the term 'genuine' instead of 'true.' People, for

instance, speak of 'true friends' and 'false friends,' 'true (genuine) diamonds' and 'false diamonds,' 'true (genuine) money' and 'false (counterfeit) money,' etc. The *objects themselves* are thus declared to possess truth or falsity. The meaning is obvious. Man has an idea of a thing in his mind, and this idea of the thing is expressed in a definition or mental judgment. This idea forms the type, the standard, the norm to which the object must conform in order to be 'true.' If the object under consideration actually agrees with this type-idea, it is 'true'; otherwise it is 'false.' In such a case, truth is an attribute of the thing and resides *in the thing*.

The truth-relation between a thing and the intellect is thus seen to be such that either the intellect agrees with the thing or the thing with the intellect. Both forms of truth have this in common that there is an agreement between intellect and thing. *Truth in general*, therefore, is the *agreement (conformity) between intellect and thing*. This is truth in its widest and most fundamental meaning. The definition does not state whether the intellect must agree with the object or whether the object must agree with the intellect. And this formulation of the definition is purposely expressed in such an indefinite manner, because truth may be had either way. The definition must cover both forms of truth, that of the intellect and that of the thing. Reversely, of course, *falsity (error) in general is the disagreement (disconformity) between intellect and thing*.

Our concept of truth and falsity, it will be observed, is evolved out of the relation which exists between objects and our own *human* intellect. This is simply due to the fact that

we are directly aware of no other mind but our own. It would be wrong, however, to think that truth exists only in the relation of an object to our own intellect. Truth must exist in the knowledge of *any intellect*, whether divine or creatural, because, wherever there is an intellect, there can be an agreement between it and an object.

From what has been said so far, it will be manifest that we must distinguish between truth and truth. This brings us to the *kinds* of truth.

KINDS OF TRUTH

Truth may be *ontological, logical, or moral*. The essential ideas underlying this classification have already been expressed in the foregoing exposition of the concept of truth, but an explanation of these kinds of truth will be of assistance in acquiring a better understanding of the nature and extent of truth.

Ontological (metaphysical, objective) truth is the *agreement of a being with the intellect*. It is of the nature of ontological truth that the intellect possesses an idea of the thing which is taken as the norm, the standard, the pattern, the type of the thing; and with this idea the thing must agree. In so far as the object agrees with the type-idea which the intellect has of this object, it is said to be 'true' — ontologically true. Ontological truth, therefore, resides in the *objects*, because they must conform to the intellect and its idea of the object. A few examples will illustrate the matter.

An artist desires to paint a picture of the Madonna. He has not seen her, but he has within his imagination an image or type which he intends to reproduce on the canvas. He paints the image. If the picture agrees with the image previously present in his mind, it will be ontologically true, because it is in conformity with the image as conceived before the painting was made. An architect plans a building, and an engineer designs a bridge; if the building and the bridge are erected according to plan and design, they agree with the preconceived idea of them and as such are ontologically true.

In the case of man, ontological truth can have only limited scope. Whenever man makes things agree with his intellect, he must take existing materials and fashion them into something which conforms to his plan. They are products of his ingenuity and skill, like buildings, machines, clothes, furniture, instruments, etc. In all these things, however, he does not make the intrinsic essence of the objects he assembles ontologically true, because they must already exist before he can use them for his purposes. The *intrinsic essence* of things is ontologically true because they are in conformity with the ideas of God who created them; He made them agree with His eternal ideas of their being.

Logical (mental) truth is the *agreement of the intellect with a thing*. Here the relation between intellect and thing is reversed: the thing is prior, and the idea posterior. This relationship constitutes *true knowledge* of a thing. It is obvious that every being has its own peculiar entity and reality, independent of the intellect which thinks of it; things are what they are, even though no mind forms an idea of

them. When, however, a mind does form an idea of a thing in order to have some knowledge of it, this knowledge will either correspond ideally with the reality or not; if it corresponds, it is 'true,' otherwise it is 'false.' The mind has knowledge of a thing when it forms ideas of its reality and unites them in a declarative judgment regarding this reality. Ideas represent reality. Truth can be had in affirmative as well as in negative judgments, so long as the fact expressed corresponds to the fact existing.

Besides ontological and logical truth, there is also moral truth, and it is defined as the *agreement of speech with thought*. When we make a judgment in our mind regarding a certain thing or fact and then make a statement in speech which expresses this judgment in words, we have 'moral' truth, because our speech agrees with our thought; but when our speech disagrees with our judgment, the discrepancy constitutes moral falsity (falsehood, lie). Thus, when a person is called upon to 'say the truth,' the meaning is that he should state, according to his understanding of the matter, what he judges to be the fact. He may, of course, be mistaken as to the real nature of this fact, but that is not the point. So long as his verbal statement agrees with his mental judgment, he says the truth, even though his statement does not actually agree with objective reality. On the other hand, if his verbal statement is the opposite of his judgment, he will be telling a lie, even though the falsehood happens to correspond to objective reality; in such a case the falsehood is intentional, while the objective truth is merely accidental.

Moral truth may be considered as a form of *ontological* truth, if we view it solely from the standpoint of an agreement between intellect and thing. The mind's knowledge is the standard in ontological truth, and the thing must conform to it in order to be true. In moral truth the mind's knowledge is also the standard to which the verbal statement, as a thing, must conform in order that the verbal statement may be considered true.

Of the three kinds of truth, *ontological truth* mainly concerns us here. Ontology treats of being in general in its supreme determinations, attributes, and categories. Ontological truth, like oneness, is a metaphysical and transcendental attribute of being and as such belongs to ontology proper. This cannot be asserted of logical and moral truth; they are not attributes of being in general. Logical truth involves the validity of our knowledge and belongs to epistemology, while moral truth has its proper place in ethics.

THE ULTIMATE FOUNDATION OF TRUTH

Because things are known by a mind, the mind possesses logical truth. The only reason, however, why the mind's knowledge about things is logically true is due to the fact that things consist of positive elements of being which the mind recognizes to be present in the things: things are 'knowable' by their positive elements of being, and it is by these elements that things are 'known' by the mind. *Logical truth*, therefore, has its foundation in the *being* of the things known, because man's mind presupposes the being

of the things 'knowable' before it can actually become 'known.'

With regard to *ontological* truth, the relation of the human mind to the things is reversed. Here the knowledge of the mind is the type or standard to which the things must conform in order to be true. This abstract knowledge is expressed in the definition, and this *definition* then becomes the standard or *type* to which a particular object must conform in order that it can be styled 'true.' The type-idea in the human mind, however, does *not constitute* or *make* the things; the beings in the world are what they are, independent of the type-idea present in the human mind. Consequently, the ultimate foundation of the ontological truth of the things in this world is not found in the human mind.

This will be clearer when we consider the fact that human *knowledge varies* from mind to mind concerning the true nature of things; regarding most things, man has *no accurate* and comprehensive knowledge at all; and of numberless beings in this world the human mind has *no knowledge* whatever. Man's knowledge is at best extremely fragmentary and subject to many errors, even in the most ordinary things. It is evident, then, that the ultimate foundation of the ontological truth of the things in this world cannot reside in the relation of agreement which these things have to the human mind. Water was 'true' water, and gold was 'true' gold, and the solar system was a 'true' solar system, long before a human mind existed to know them. But if these things possess ontological truth in their being *after* a human mind comes to know them, they

must have possessed a *fundamental* ontological truth *before* a human mind came to know them. Obviously, then, the type-ideas of the human mind are not responsible for the ontological truth of things, so as to be the ultimate foundation of their ontological truth.

Nevertheless, there can be no ontological truth in the things except in so far as they conform to an intellect and its type-ideas of these things. Since the intellect in question cannot be the human intellect, there must be some *intellect other than human* to which all things must conform; they will then owe their ontological truth to their agreement with this intellect. Ontological truth, as we have seen, lies in the *intrinsic reality* of the things; that intellect, then, will be the ultimate foundation of their ontological truth which is the ultimate foundation of their intrinsic reality. We thus see that the very reality and nature of all the things in this world demands an intellect over and beyond the world itself, and that is the Divine Mind. God gave all things their intrinsic reality by creating them. He created them according to the *exemplars or type-ideas* which He had of them before He gave them existence. These exemplars were, therefore, antecedent to the existence of the things created. By being created, the creatural things were made to *conform to God's ideas* of them, and therein consists the *ontological truth* of their being.

Even God's *infinite essence* possesses *ontological truth*. He is a being, a reality; as such, He is a 'true' being, 'true' reality. The agreement of His essence to His mind is an absolute agreement, because it is identical with it. God, therefore, is Truth. God is absolute, eternal, infinite

ontological Truth; creatures *have* relative, temporal, finite ontological truth. And this applies as well to all *possible* beings: they possess ontological truth, because they are in conformity with the type-idea which God has of them in His mind. Ontological truth, therefore, is an essential attribute of all being, divine and human, actual and possible, necessary and contingent. Consequently, *the ultimate foundation of all truth consists in the essential conformity of all things to the Divine Mind.*

CONVERTIBILITY OF BEING AND TRUTH

‘Being’ and ‘truth’ are convertible. This is to say: Every ‘being’ is ‘true,’ and whatever is ‘true’ is a ‘being.’ That should be clear from what has just been said.

Every being is either potential or actual; it is either finite or infinite. The *finite* being, whether actual or potential, has its actual or potential reality only because God can think it and make it. God, however, can think it and make it only because it is in some manner an imitation of His essence. But by imitating His essence they imitate His ideas, because His essence and ideas are identical in reality, due to the infinite perfection of His being (as will be shown in theodicy). Finite beings, therefore, whether actual or potential, have reality only by agreeing with the ideas of God. To agree in their reality with God’s ideas means to agree with His intellect; and that means to be ontologically true. Consequently, every finite being is ontologically true.

God is *infinite* essence. There is a conformity of His essence with His ideas, because His essence is identical

with His ideas; and this is the most exalted and perfect conformity possible. God's infinite essence, therefore, is ontologically true. Now, God's infinite essence and all finite beings, actual and possible, comprise all being. Consequently, all being is ontologically true, and *ontological truth is a transcendental attribute of being as such.*

We may even speak of all things as *ontologically* true in their relation to the *human* mind. This, of course, does not mean that the human mind has the correct idea of all things or even has a knowledge of all things; that would obviously be false. What is meant is simply that all beings, by the very fact that they are entities, have positive elements of essence and as such are intelligible, even though they are not actually known by the human mind. The mind *can know* them. So far as their reality is concerned, they are such that the human mind can make true *ideas and definitions* of them, to which they will always conform. Hence, even with regard to the human mind, things possess a *potential and fundamental*, if not an actual and formal, ontological truth.

Every being, then, is true. In order that 'being' and 'truth' be convertible, it will also be necessary to show that everything which is 'true' is a 'being.' The proof is simple. We have just shown that every being is true. Ontological truth is, therefore, a transcendental attribute of being. As an attribute of being, this ontological truth must be something. If it were not something, it would be 'nothing,' and 'nothing' cannot be the attribute of anything. But if ontological truth is not 'nothing,' it partakes of the nature of 'being.' Consequently, whatever is ontologically 'true' is a 'being.' Ontological truth and being are thus seen to be

convertible and identical: they are the same reality, viewed from two different standpoints.

THE EXISTENCE OF FALSITY

By falsity we understand the disconformity between thing and intellect. As there are three kinds of truth, there are also three kinds of falsity: moral, logical, and ontological.

Moral falsity is the disconformity of speech with thought or judgment. It is also called falsehood or lie. That lies are told, needs only be mentioned. *Logical* falsity is the disconformity of the intellect to the thing. 'Error' is another name for it. That logical falsity is often present in the mind is palpably demonstrated by all the mistakes, confused opinions, and conflicting systems of thought existing throughout the world at all times. The very fact that we change our views and correct our judgments is the surest indication that logical falsity occurs frequently in our judgments about persons, things, and events. There can be no question about the occurrence of moral and logical falsity.

The matter, however, is very different when we speak of the occurrence of *ontological falsity*, the disconformity of thing to intellect. Can we really apply ontological falsity to things? We certainly speak of false peace, false culture, false diamonds, false friends, false ideals, false teeth, and so on. In order to avoid confusion, we must distinguish between ontological falsity in an absolute and in a relative sense.

In an *absolute sense* there can be *no ontological* falsity. A thing that is ontologically true cannot be ontologically false; that would be a contradiction in terms. But every being is ontologically true, as we have just proved. Consequently, no being or thing can be ontologically false. In order to be ontologically false in an absolute sense, it would be necessary that such a being disagree with every possible intellect; if it agreed with a single intellect, it would no longer be ontologically false, but ontologically true. Now, every being, in so far as it has any reality at all, must always agree with the intellect of God, because it could not be what it is unless it agreed with His intellect: it is what it is, because God created it according to the type-ideas in His intellect. Hence, every being is ontologically true with regard to the ideas of God.

In a *relative sense* we may speak of ontological falsity, namely in relation to the *human mind*. That we do not always succeed in making the products of our skill and art agree with the plan or type we have in our mind, is a matter of almost daily occurrence. An artist is seldom satisfied with the work of art he produces. A typist intends to make an error-free copy, but all too frequently she will find a mistake. A builder seldom erects an edifice which is perfect in every detail of the plan. The mechanism which an inventor constructs does not always perform as smoothly as the genius of its maker expected. In the case of imperfect *artificial products*, therefore, we may legitimately speak of relative ontological falsity.

We do not, however, restrict the term 'ontological falsity' to artificial products made by man; we apply it very often to

natural things. Thus, we speak of German silver as 'false silver'; or we say that it is not true, not genuine silver. What do we mean? We mean that it has the general *appearance* of silver, and the mind in consequence is apt to judge that it is true silver. This, of course, would be a *false judgment*, since German silver is only an alloy of copper, nickel, and zinc. Hence, by means of an extrinsic denomination or analogy we transfer the falsity, which is really only in the judgment (logical falsity), over to the object itself (ontological falsity). But German silver is really and truly what it is, namely copper, nickel, and zinc, agreeing perfectly at all times with God's type-idea of it; and so it is always ontologically true with reference to God's mind. As a matter of fact, even with reference to man's intellect German silver cannot be said to be really ontologically false, because not all human minds will be deceived into judging it to be true silver; this is proved by the fact that we actually do know the composition of German silver as an alloy of copper, nickel, and zinc. If it were *really* ontologically false with reference to the human mind, no human mind would be able to discover its component elements.

No matter, then, what the appearances of things may be to man, they have an *intrinsic constitution* which is always ontologically true, at least so far as the mind of God is concerned; for man they may, of course, be the *occasion* of false judgment. 'False diamonds' are 'true paste'; 'false teeth' are 'true porcelain'; 'false virtue' is 'true vice'; 'false gold' is 'true pyrite'; 'false economy' is 'true waste'; 'false faces' are 'true masks': their true nature *can* be known by man and is known always by God. In an absolute sense,

therefore, ontological falsity does not apply to any being; in a relative sense, namely with reference to man, ontological falsity may be said to exist in a limited manner. Ontology, since it views all things from a metaphysical standpoint, treats of things in their intrinsic reality, without regard to the impression they may produce upon a fallible human mind; considered metaphysically, all beings, of whatever kind and nature, are and must be *ontologically true* under all circumstances.

SOME CHARACTERISTICS OF TRUTH

Truth is *primarily in the intellect*, not in the things. The whole import of language testifies to the fact that truth is considered to be principally a qualification of *knowledge*. Knowledge is 'true,' and knowledge is 'false'; judgments are 'true,' and judgments are 'false.' Even when speaking of God, truth is primarily predicated of His knowledge and His mind, not of His essence. Only secondarily, by means of an analogy, is truth attributed to the reality of things. For created minds the reality of things is the cause of logical truth, in as much as this reality makes an impression on the mind and enables it to conform to the thing; for this reason we call things 'true,' and this analogy is an analogy of attribution, just as food is called 'healthy' because it causes health in a body. *Ontological, transcendental truth*, however, is not applied to things fundamentally for the reason that they are the 'cause' of true knowledge. With regard to created minds this is clear, because every being is transcendently true, independent of all created minds.

Nor can we say that their transcendental truth is due to the fact that they cause God's knowledge to be true, because things cannot produce any effect in the Infinite Being; God's knowledge of them is true antecedent to their existence, and they possess ontological, transcendental truth precisely because they agree in their reality with the knowledge of them which exists in God's mind from eternity. They are made to conform to God's intellect, and because of this essential conformity of their reality to God's intellect, they are said, by an *analogy of proportion*, to be ontologically 'true.' True knowledge, and therefore truth itself, is primarily an attribute of God's intellect and only secondarily an attribute of things. Hence, truth is primarily in the intellect, not in the things.

It is frequently asserted that *truth is eternal*. Is this assertion correct? If we speak of God as the First Truth, it is evident that it must be eternal, because it is identical with His essence. If we speak of *created truth*, we must distinguish. *Logical* truth in creatural minds is not eternal in itself, because these minds are not themselves eternal, but temporal, and logical truth resides in these created minds as a qualification of their knowledge; this logical truth is, therefore, also temporal in character. Neither is the *ontological* truth of created beings, considered in itself, eternal; their ontological truth consists in their entity, viewed as conforming to (God's) intellect, and since their entity is created and temporal, their ontological truth must also be created and temporal. Considered, however, from the standpoint of God's eternal knowledge and power, created truth can be said to *be eternal with a sort of*

extrinsic eternity. This means, that things are eternally true, not because they possess any reality in themselves which would be eternal (for that is created and temporal) but because their reality (whether possible or actual) is eternally in conformity with God's eternal knowledge of them. Thus, it is eternally true that man is a 'rational animal,' because that is God's eternal idea of 'man,' even if as a matter of fact man himself is a created and temporal being so far as his existence is concerned.

This will also explain in what sense it can be said that *truth is immutable*. If something is eternally true, it is also immutably true. As 'things' things change, and their ontological truth changes with them. But if we consider their conformity to God's ideas of them, all created beings (whether possible or actual) are immutably true, because they must always agree with God's knowledge of them, even when they change in their being from moment to moment.

THE TRUTH OF CONTINGENTLY FUTURE EVENTS

Can judgments or statements about contingently future events be styled 'true' or 'false'? The question raises an interesting problem. In order to understand the issue properly, it will be necessary to explain the meaning of *contingently future events*.

It is *not* a question here of future events which are *predetermined* in their physical causes, so that they must and will happen according to the laws of nature. Such future events would be, for example, eclipses of the sun and

moon. Events of this sort are in themselves predictable, provided one has a sufficient knowledge of the causes which will produce this particular effect. The judgment that 'A solar eclipse will take place at 10:00 a.m. on July 4, 1960' is at this very moment definitely true or false. There either will be an eclipse at the time designated, or there will not; if there will be, the statement is true, and if there will not be, the statement is false. Such events of the future are not contingent; they are *determined* events, and there is no question about the truth of their occurrence or non-occurrence, even if we do not know them.

It is a question of *contingently future events*. A contingent event is one that can, but need not, occur; and if the event is a matter of the future, it is a contingently future event. It is an event which may or may not take place in the future, and the doubtfulness of its occurrence results from the fact that it is *not predetermined* in its cause. Rather, the cause is of such a nature that, although every requisite for action is present, it can act or refrain from action. This will be the case when an action or event is dependent on the decision of a *free will*. In the presence of all conditions necessary for action, a free will can perform the action or omit the action. For example: Shall I walk to the library tomorrow? This walk is a contingently future event, because it depends on my free choice. I myself do not know at the present moment whether I will or will not take this walk. Two statements are possible here: 'I shall walk to the library tomorrow' and 'I shall not walk to the library tomorrow.' These are contradictory statements, and one of them should be true and the other false.

Some philosophers claim that 'truth' and 'falsity' cannot be applied to contingently future events of this character. Neither of these two statements can be styled 'true' or 'false' *at the present moment*; they can become 'true' or 'false' only after the will makes its decision at the time of the event's occurrence, but not before. Other philosophers contend that one of these two contradictory statements is true and the other false *at all times*, whether present or past, and even from eternity. Who is right? Having specified the problem as given above, we must say that contradictory statements of contingently future events which depend on the free will are simply, as future events, *definitely true or false in themselves*. As such they are known to God from all eternity. And now for the demonstration.

Let us take the two contradictory statements given above, namely 'I shall walk to the library tomorrow' and 'I shall not walk to the library tomorrow.' Since these statements are contradictory, one of them will be *definitely true tomorrow* and the other definitely false. Supposing, as a matter of fact, I actually do walk to the library tomorrow afternoon. Then, as I walk, my walking to the library is a present definite occurrence, and the first statement is *then definitely true*; the second statement will of necessity be definitely false. In that case, however, if anyone states *today* that 'I shall walk to the library tomorrow,' he is making a statement which is also *definitely true today*, even though he is speaking of an event which is contingently future today and will only occur tomorrow. But if a contingently future event is definitely true at the present moment, it was also definitely true yesterday and last year and from all

eternity. And since God, who is infinitely perfect in His knowledge, must know all truth, He also knows all contingently future events, i.e., those dependent on the choice of free will.

The same argument can be formulated in a slightly different way. That I am writing *at this moment*, is an event which is dependent on my free will; I decided to write, and I am writing now. *Yesterday* my present writing was a contingently future event. Since, however, my writing is here and now a definitely true event, I can obviously make the definitely true statement that 'I am writing.' If, then, I had made the statement yesterday that 'I shall write tomorrow,' it would have been a definitely true statement yesterday; on the other hand, the contradictory statement would have been a definitely false statement. But if it was definitely true yesterday, it was definitely true for the whole past and from all eternity.

A past event is definitely true in itself, irrespective of whether its occurrence is due to a necessarily acting or freely acting cause; and since it occurred, the statement of its occurrence is definitely true, simply because of the entity and existence which it *then had in itself*. A *present* event can also be expressed in a definitely true statement, even if it be due to the free will, simply because of the entity and existence which it *now has in itself*. And for the same reason a *future* event, whether necessary or free, is definitely true in itself and can be expressed in a definitely true statement, simply because of the entity and existence which it will *then have in itself*. When the future event actually happens, it will be a fact; consequently, it is even

now a true future fact and can, absolutely speaking, be expressed in a statement which is also true. That man, in the weakness and limitation of his knowledge, cannot know these contingently future events, is beside the point: future events being future facts, God must know them simply because they *will* happen.

God's knowledge of contingently future events does not in any way militate against the freedom of their causes in acting. Such events will not happen because He knows them; He knows them because they will happen. Knowledge, whether past, present, or future, does not necessitate any action, because it is not the cause of the action. If an event is produced through a necessary cause, God will know the event as such, and if it happens as the result of free choice, God will also know that as such. All events without exception possess *ontological truth* in themselves and must conform to the intellect of God, because His mind encompasses everything that is true. That all contingently future events really possess ontological truth, is obvious: in all contradictory statements regarding such events (for instance, 'I will walk' and 'I will not walk'), one of these statements must agree with the actual event which will happen in the future, for it is impossible for both to happen and for neither to happen, due to the Principle of Contradiction and Excluded Middle; and the one alternative of the contradiction, the event which will actually occur in the future, will have reality and existence, and as such has ontological truth. Since, however, all ontological truth agrees with God's intellect, God knows it before it happens.

Such is the nature of truth. It is a transcendental attribute of all being, creatural and divine, possible and actual, necessary and free, past and present and future.

SUMMARY OF CHAPTER XIII

Just as every being is 'one,' so it is also 'true.' Truth is a transcendental attribute of being as such.

1. *Concept of Truth.* We arrive at the concept of truth from our own experience. Truth is true knowledge and consists in true judgments, in so far as our *judgments* agree with reality as it is in itself.

There is also truth in *things*. The definition of a thing is the norm or type to which things must conform in order to be called 'true.' Truth in general, therefore, is the *conformity between intellect and thing*. Falsity is the *disconformity between intellect and thing*.

2. *Kinds of Truth.* There are three kinds of truth: ontological, logical, and moral. *Ontological* truth is the conformity of a thing to the intellect. *Logical* truth is the conformity of the intellect to the thing. *Moral* truth is the conformity of speech to thought. Ontology is mostly concerned with ontological (metaphysical, objective) truth.

3. *The Ultimate Foundation of Truth.* *Logical* truth depends on the positive elements of being present in a thing, because it is the conformity of the intellect to the thing; its foundation, therefore, is the being of the thing known. Ontological truth, since it is the conformity of thing to intellect, must have its ultimate foundation in that intellect which is the ultimate foundation of the intrinsic reality of things. This is not the human intellect, but the intellect of God, according to whose type-ideas all things have been created. Even God's essence conforms to His

intellect, because it is identical with His intellect. Hence, the *ultimate foundation* of all truth. logical and ontological consists in the essential conformity of all things to the Divine Mind.

4. *Convertibility of Being and Truth.* Finite beings and also the infinite essence of God are all in conformity with His mind and as such are ontologically true. Therefore, every being is 'true.' Truth is a transcendental attribute of being, as just shown; since an attribute is not nothing, it must be something, and as such it partakes of the nature of 'being.' Consequently, all being is true, and whatever is true is a being.

5. *The Existence of Falsity.* That moral and logical falsity (lies and errors) occur, is a matter of daily experience. In an *absolute* sense, *ontological* falsity cannot exist, because all beings are transcendently true and agree at least with the Divine Mind. In a *relative* sense, i.e., with regard to the agreement of things with the human mind, things may be ontologically false in a limited way; products of skill and art often deviate from the plan in man's mind. If natural things are called 'false,' it is only because their appearance is the occasion of false judgments for man.

6. *Some Characteristics of Truth.* Truth is *primarily in the intellect*, not in the things. Truth is primarily considered to be a qualification of knowledge. Ultimately all things are true because they agree with God's knowledge; truth, therefore, resides primarily in God's knowledge and secondarily in the things.

Truth can be said to be eternal in so far as God's knowledge, with which all things must agree, is eternal.

And in so far as God's knowledge is immutable, the truth of things is also *immutable*.

7. *The Truth of Contingently Future Events*. Events are contingently future when they are dependent on a free-acting cause; the free will of man is such a cause. Can such events be termed 'true' or 'false'? They can. Contingently future events can be expressed in two contradictory statements, one of which must agree with the event that will happen; this statement will be true and its contradictory false. Since the future event will have ontological truth when it happens, it must agree with God's knowledge. God's knowledge being eternal, the contingently future event must be known by God from eternity.

Chapter 14

BEING AND GOODNESS

SO FAR WE HAVE CONSIDERED TWO TRANSCENDENTAL ATTRIBUTES or properties of being, namely, unity and truth. Being, considered in itself, in its inner constitution, is undivided, one; it has the property of oneness or unity. This is an absolute property of being, because it pertains to every being, irrespective of the fact whether other beings exist or not. Being, considered in relation to a knowing intellect, is true; it has the property of truth. Truth always involves the relationship of intellect and thing, and truth is, therefore, not an absolute but a relative property of being. And just as being always has a relation to intellect and thus is true, it also has a relation to appetency and as such is *good*. 'Goodness,' with 'unity' and 'truth,' is a transcendental property or attribute of all being.

THE CONCEPT OF GOODNESS

Like the concepts of 'being,' 'one,' and 'true,' the concept 'good' is a primary and fundamental concept of the human mind. It is more easily recognized in the concrete than analyzed in the abstract. We can point it out more readily

than define it. We can, of course, define it in a descriptive manner, but the defining terms will, as a rule, hardly be more clear than the term to be defined. We must, therefore, begin by consulting our experience of the 'good' and end by formulating our experience in a descriptive definition.

When are things said to be 'good'? *Aristotle* gives this definition: "Good is what all desire."¹ A thing is good in as much as it is appetible or desirable; goodness, then, consists in the appetibility or desirability of a thing. Now, this is really a definition of the good by its *effect* in another being, namely, by the desire engendered by it in some being. This does not tell us anything about the thing itself, *what* in it is such that others should desire it. Why do things desire something? Evidently because this something is considered to be 'good' for it. Desirability or appetibility, therefore, presupposes *something in the thing* which is 'good' and on account of which it is actually desired or is at least desirable. There must be something positive in a being which influences another and causes this other to desire it as 'good,' and it is precisely this characteristic which must constitute its 'goodness.' What is it?

What a thing desires or seeks as good in another, depends entirely on the sort of individual the thing is. A magnet seeks iron, an ionized atom seeks a stray electron, a bee seeks honey, a lion seeks food, a plant seeks sunlight, a man seeks knowledge, etc. It would be useless to attempt to discover the various kinds of 'good' which each individual being strives for in the course of its existence. We must attempt to discover the *general feature common to all things* that are styled 'good,' if we wish to arrive at a

fundamental concept of goodness. Viewed in this light, we find that a being strives for something as good because the latter satisfies some need, some demand, some exigency, some natural tendency or aptitude; it helps it in some way, or completes it in some fashion, or gives it pleasure in some form, or actualizes some potentiality of its nature, or has the capacity to realize some end and purpose in it. These various viewpoints express the one fundamental fact that a thing is good because it agrees with some natural tendency or appetency. *Goodness*, therefore, is *the suitability of a thing to a natural tendency or appetency*.

‘Natural tendency’ or ‘appetency’ is used here in a very wide sense and includes every kind of *striving power*. This striving power may be a conscious appetency, as we observe it in man (rational appetite) and in the animal (sensuous appetite); or it may be unconscious, as we perceive it in the affinity of chemical elements. The affinity between protons and electrons to form an atom, or between chlorine and sodium to form salt, or between hydrogen and oxygen to form water, is as manifestly an instance of ‘natural tendency’ as is the striving of a cat for milk or of a man for knowledge. In each case we have the satisfaction of some natural need and demand, of some appetency,’ but in different ways. It is obvious, too, that in each case the one is ‘good’ for the other for that very reason.

By the very fact, though, that beings have such tendencies and appetencies, it is clear that they cannot have their *complete actuality* from the beginning. If they had all their entity, if they possessed all the reality they are capable of receiving, they would no longer tend toward, or

strive for, anything. To do so means that there is still some potentiality in their being which needs and demands realization. And in so far as something is suitable for this fuller realization and actualization of a being, it will be 'good' for it. What, in particular, is suitable to a being, will naturally depend upon what this being *needs* and what the other being has *to offer* for the satisfaction of this need. To designate each particular need of a being and its corresponding good would require a detailed description of each individual being — a task both impossible and unnecessary. This will explain why the definition of 'goodness' is worded so vaguely as the 'suitability of a thing to some natural tendency or appetency.' To define a good more closely would require a catalogue of individually suitable realities, and that would reach far beyond the scope of ontology which seeks to determine the 'good' in its widest and most fundamental concept, applicable to every type of specific and individual 'good.'

The general concept of 'good,' therefore, consists in this that something is suitable to a thing. Now, all beings have a nature of essence peculiar to themselves as members of a class and as individuals. And each such nature has a very real and definite *Purpose or end within itself* which it tends to bring to full completion and *perfection*. A thing is perfect when it has everything that it is supposed to have according to the exigencies of its nature. Perfection, then, is the full actualization of a being according to the exigencies of its nature relative to the purpose or end of its essence. This may be taken absolutely or relatively. Absolute individual perfection would be the complete and final actualization of

a being in its totality; relative individual perfection would be the actualization of a being at a particular *stage of its development* as demanded by it at this point. In either case it would at the moment have as much reality as its nature demands.

For instance, a chemical element has a limited nature whose purpose or end reveals itself in its tendency to unite with other related elements so as to form a definite compound with them. A plant has the natural purpose of developing as a vegetant body into a mature plant. A brute has the natural purpose of realizing itself as a sensuously conscious animal to the full extent of its powers. Man, being a rational animal, has the natural purpose of actualizing himself as a fully developed sense-organism and rational person. What serves man's natural end or purpose would not necessarily be good for a being in a lower order; and what serves the purpose of a chemical compound or plant need not be good for a brute or man. Each nature thus implies a specific natural tendency within itself, and things will be 'good' for it in so far as they suit its nature. Nothing, however, will suit the nature of a being more than the very entity of this nature; that is an 'intrinsic' good for a being. Consequently, all natures or *essences are good* for the individuals who possess them. On the other hand, any *outside beings* which help to develop or actualize their natures or natural tendencies will be good for them; they are an 'extrinsic' good for a being. Sunshine, for example, is an extrinsic good for a plant: food, for the bodily welfare of man.

In the light of this analysis of the data of our experience we find that the concept of 'good' and 'goodness' has a very wide range of application. And thus we may eventually define the *good* as any *reality which suits the nature of the being which strives for it*. This definition would fit the nature itself which desires and strives as well as the reality which this nature desires and for which it strives. 'Goodness' in the abstract would then be defined as the suitability of a reality for the nature of the being which strives for it.

CLASSIFICATION OF GOODNESS

There are various standpoints from which we may view the good, and correspondingly we may distinguish between different kinds of good. The main divisions are as follows:

Ontological, Physical, Moral Good. A thing is an ontological good, when it is a good in its very *entity or reality*. Every being, since it possesses a certain amount of entity or reality, is an ontological good; this is due to the fact that its entity or reality is suitable for the tendency of its own nature to be what it is and to perfect itself and to retain its perfection. In as much, too, as things are good in themselves by possessing their own entity, they are capable of being desired and striven for, so as to perfect the nature of some other thing. Ontological goodness is also called 'transcendental' or 'metaphysical' goodness, because, like unity and truth, it is convertible with being. All beings are thus an ontological good, considered in themselves and for themselves.

A thing is a *physical* good, when it satisfies the demand of the *nature of a being*. Each being has its own specific and individual nature, and as such it has a very definite end and purpose. The physical exigencies of man, for instance, differ from those of a horse, a cow, a cat, an oak, or an apple. He is supposed to have a head, a trunk, two arms, and two legs; two eyes, two ears, two hands, two feet; well-functioning organs of sense, digestion, locomotion, etc. These things, for man, are physically good, and none of them may be missing or defective, if man as a whole is to be considered physically good. And so it is with every physical being.

A thing is a *moral* good, when it has everything demanded of it by the *moral law*. An action may be ontologically and physically very good, but it may be morally very bad. An example will clarify this statement. A soldier defends his country in a just war. In an attack by the enemy, he kills an enemy soldier with his rifle. On another occasion an enemy soldier comes toward him, carrying a flag of truce; him he also kills with his rifle. In both cases his action kills a human being: in so far as the action is an entity, it is ontologically good; in so far as his aim is true and physically successful for the purpose of man-killing, it is physically good. But there is a difference in the morality of the action in the two cases. In the first it is justifiable homicide and morally good, because it is in accord with the moral law which demands of him the defense of his country as a duty; in the second it is murder and morally bad, because the moral law requires that he respect the enemy's person when he carries a flag of truce.

Absolute and Relative Good. This is another division of 'good.' An *absolute* good is anything which is suitable *to a being itself*, irrespective of other beings. Any reality which a being possesses, whether substantial or accidental, is an absolute good. A *relative good* is anything which is suitable to another being. Thus, human nature, including every part and function which belong to this nature, is an absolute good for man. Food, drink, clothes, shelter, etc., are a relative good for man. Absolute and relative *good*, however, must not be confused with absolute and relative *perfection*; the concepts are by no means synonymous. Perfection always implies that a being have everything that it is supposed to have according to the requirements *of its nature*, either its complete and final actualization (absolute perfection) or that amount of actualization which it requires at a particular stage of its development (relative perfection). But the actualization of any nature is an absolute good for itself; hence, perfection, whether absolute or relative perfection, is a subdivision of 'absolute good,' and it cannot be a 'relative good,' since the latter is always a good for another. Again, a being may be good without being perfect. For example, if a man is blind in one eye, his vision is still an absolute good for him, but this vision is imperfect, because man is supposed to have vision in both eyes. It may be well to remember, however, that terms like 'perfect' and 'perfection' admit of a variety of interpretations, and in many instances 'goodness' and 'perfection' are used more or less synonymously; the context of the discussion will then fix the meaning of the terms employed.

Objective and Subjective Good. By *objective* good we mean anything that is good in *itself*. Any absolute or relative good, as just defined, is an objective good in this sense. By *subjective* good we mean the actual possession of an objective good. Thus, a diamond ring, considered in itself, is an objective good; the ownership and possession of it is a subjective good for the one who owns and possesses it.

Real and Apparent Good. A good is *real*, when it is judged to be good for a being, and it *actually is* good for that particular being. Such is physical well-being for an animal, knowledge for man, sunlight for a plant, rain for the soil, etc. It is an *apparent* good, when it is judged to be good for a being, but it is *actually not good* for it. Food may seem a 'real' good for a critically ill patient, but it may be very harmful; under the circumstances it is an 'apparent' good. Pleasure is a physical good; but if its enjoyment is in opposition to the moral law, it is an 'apparent,' rather than a 'real,' good. This does not mean, of course, that such things are not ontologically or physically good in *themselves*; as such each is a real good. Relative *to another*, however, they may do harm; viewed from this standpoint, they are an apparent and not a real good. The difference of standpoint for the judgment should be carefully noted; the difference is often overlooked, resulting in a serious confusion of ideas and ideals. Thus, love of country, when it engenders in the citizenry a great spirit of service and sacrifice for the welfare of all, is a lofty patriotism and a real good; but when it urges national aggrandizement at the cost of right and justice, it is a false ideal and only an apparent good.

The distinction between real and apparent good is especially important in the case of man as a composite being of *body and soul*. He is a rational animal. This composite nature of man gives rise to conflicting tendencies and needs. As an animal or sentient being, he may crave for satisfactions in a multitude of ways. As a rational or moral being, he may desire and demand satisfactions of a sort at variance with those of his natural body. The result will be a conflict between his 'higher' and 'lower' tendencies, and in this conflict tendencies of a rational and moral character must obtain primary consideration, because man is distinctively 'human' in consequence of his rational and moral nature. A proper balance must be struck between these opposing tendencies and needs. To accede to the lower demands at the expense of the higher would be irrational and immoral. *For man*, therefore, considered as a rational and moral being, much that is a physical good for his body must be adjudged an 'apparent,' and not a 'real,' good for his person.

Disinterested, Delectable, and Useful Good. A *disinterested good* (*bonum honestum*) is any good considered merely as giving perfection, irrespective of any pleasure derived from its possession. The perfection which the disinterested or upright good is capable of conferring may be physical, intellectual, or moral in character. Health, knowledge, and virtue are such. A *delectable good* (*bonum delectabile*) is a relative good which gives pleasure and enjoyment to another. What is really desirable here is the thing itself which gives pleasure; oftentimes, however, the pleasure itself becomes the object of desire. Food, drink,

and the proper use of sex are delectable goods; in many instances, though, the pleasure which accompanies these things becomes the sole object of the will. A *useful good* (*bonum utile*) is a relative good which is desired as a means to acquire perfection or pleasure. There is always an ulterior end in view when a good of this kind is striven for. Examples are: clubs, balls, and links, for a game of golf; automobiles, trains, airplanes, and boats, as means of transportation.

GOODNESS AND VALUE

Much is written by modern philosophers on *value* and the metaphysical nature of value. In so far as we are interested in a thing, care for it, desire it, seek it, strive for it, this thing shows itself to be invested with 'value,' to be 'valuable.' Wherein precisely does the 'value' of a thing consist? Why is it considered 'valuable'?

Obviously, to be 'valuable' and to be 'good' are closely related terms; for something is said to be 'good' when it is the 'object of desire,' when it is 'suitable' for a being, and that, as will be observed, is practically equivalent to saying that it possesses 'value.'

The immanent and final end and purpose of every being is its own *perfection*. All things which a being desires and seeks are desired and sought in order to realize this ultimate end and purpose. Whatever, then, helps to perfect it, is in so far 'good' and 'valuable' for it; it is viewed as means to this end. Ultimately, of course, this perfection is

also desired and sought and so becomes the ultimate, intrinsic 'good' and 'value' for the being.

Value, therefore, can be viewed either as an end or as means. As the ultimate and intrinsic end it is the perfection of a being. As means it is the capacity or suitability of a thing to perfect another. 'Value,' then, is either perfection itself or the ability to give perfection; whatever is perfect or is perfective, is thereby 'valuable.' Hence, we can define *value* as that which is *perfect or perfective*.

What, then, is the *relation* between 'goodness' and 'value'? Value, considered as perfection, coincides with the absolute or intrinsic good, because it is identical with the reality, substantial and accidental, which a being possesses. Considered as perfective, it is the relative or instrumental good, because its perfection is a good for another being. Everything, therefore, has value in so far as it is a good for itself or for another.

'Goodness' and 'value' are thus seen to be synonymous terms, when viewed in their metaphysical implications.

THE CONVERTIBILITY OF BEING AND GOODNESS

Goodness, like unity and truth, is a transcendental and meta physical attribute of being and as such convertible with it That is to say: Every being is good, and whatever is good is being.

Every being is good. This, of course, must be rightly understood. It means that every being is *ontologically good*; every being, in so far as it is a reality at all, is good. An individual nature need not be a perfect specimen of its

class; it may be very imperfect and even defective in many respects. Nevertheless, the entity that it actually possesses is ontologically good. The correct sense of the thesis, therefore, is this: Every being in so far as it is a positive reality, possesses intrinsic or *Ontological goodness*.

Every being is either a substance or an accident and as such has its own individual nature and essence. Whatever is suitable for a nature and essence is good. But nothing could be more suitable for the nature and essence of any thing than the very *entity* of this nature and essence. The entity, however, of the nature and essence of a thing makes this thing to be a 'being.' Consequently, every being, i.e., every substance and accident, is entitatively or ontologically good. Hence, every being is good.

St. Thomas Aquinas formulates his argument in the following manner: "Every being, in as much as it is being, is in some way perfect, because every actuality is a certain perfection. But what is perfect involves the idea of 'appetible' and 'good.' Hence it follows that every being as such is good."²

Besides, all beings are the object of Divine Omnipotence and therefore also of the Divine Will, in as much as God either directly wills them or indirectly permits them to exist and have their being. Hence, they agree with His appetency or will. But for anything, in its existence and being, to agree with God's appetency or will, means that it is ontologically good. Hence, all things are good.

And just as every being must be an ontological good, so also *whatever is good is a being*. This hardly needs demonstration. The 'good' is certainly not nothing, but

something; it is something desirable, something suitable. 'Nothing' is not suitable for anything and as such cannot be the object of an appetency. Consequently, whatever is good is a being. The concept of the 'good' always implies the concept of something positive, some reality or actuality, something that can perfect its possessor. This, however, implies that whatever is good is a 'being.' Hence, every good is a being.

THE CONCEPT OF EVIL

Evil is the antithesis of good. As the good in general means the suitability of a thing for an appetency or appetent being, so *evil* is the *unsuitability of something for a natural tendency or appetency*. This definition might seem to indicate that 'something' can itself be an evil, so that evil would be a positive reality of some kind. That would be a misunderstanding of the meaning.

Evil is no being, but it is not a mere absence of being. It is the absence of a reality which ought to be there, of a *reality due a thing*; it is a defect, a *privation of reality*. An example will make this clear. There is an absence of sight in a stone; the stone is 'sightless.' This sightlessness is the absence of a reality in the stone, but is no evil for it. When there is an absence of sight in a man, he is said to be 'blind,' not merely 'sightless' like a stone. This blindness in man is not a mere absence of a reality; it is an 'evil' for him. What is the difference between a stone and a man in this absence of sight, so that the former is considered to be merely 'sightless,' while the latter is declared to be 'blind'? Why is

sightlessness for the stone a mere absence of perfection or reality, and for man an evil? The difference is this: sightlessness in man is the *direct defect* of a good which ought to be there, and that constitutes it an evil for man; the stone, however, is not supposed to have sight, and consequently its absence is no direct defect or evil for it, but only the absence of a reality not due its nature.

It will thus be observed that the concept of 'evil' does not imply a positive reality, but a *strict privation* or defect, namely, the privative lack of an entity due a being. Since evil is essentially a privation or defect of entity, it must be obvious that it cannot exist for itself but always *presupposes a subject* which lacks something which the subject ought to have; as such it is always something *relative*, i.e., relative to the individual nature in which the defect is found. But, if evil needs a subject which it affects, is then evil not an 'accident'? It is not. An accident is a positive reality inherent in a subject, contributing some positive entity or determination to its subject, while evil is a defect of a being in its subject: between the two lies the difference between an 'entity' and a 'privative nothing.' Evil, therefore, can also be defined as the *privation of a required good* (*privatia boni debiti*).

KINDS OF EVIL

Since evil is the privation of a good, there will naturally be as many kinds of evil as there are kinds of good. The following are typical.

Ontological, Physical, and Moral Evil. An *Ontological* (metaphysical, transcendental) evil is the privation of an ontological good. Strictly speaking, this means that a thing, *as a being*, is evil in itself. The question, whether an ontological evil as such can exist, will be treated shortly; at present we are concerned only with its concept and definition.

A *physical* evil is the *privation of a physical good*. Thus sickness is a physical evil, because health, of which sickness is the privation, is a physical good. The absence of any member, organ, or function, which normally belongs to a being of a certain class, will be a physical evil. Such would be the absence of a finger or an arm in man, of a tail in a dog, the loss of sight or hearing in a mammal. This applies, of course, merely to the individual member, organ, or function considered for itself. That the removal of an inflamed appendix or other part of a body may be, indirectly and relatively, a physical good for the organism *as a whole*, is obvious; the physical good of the whole always supersedes the physical good of a part of the whole. For the organism as a whole, general debility, sickness, or death would be physical evils.

A *moral* evil is the *privation of the proper relation* between an action or its omission and the *moral law*. If the moral law demands a certain action and this action is unduly omitted, the omission is a moral evil. Man, as a creature, for example, is obliged to recognize the sovereignty of God and adore Him; if he fails to do this, the omission is a moral evil. On the other hand, the moral law may forbid a certain action; if the action is performed

nevertheless, it will be a moral evil, because the proper relation between the law and the action is not maintained. The cashier of a bank, for example, may withdraw his own money from the bank and spend it, but if he takes other people's money and spends it, he is guilty of a crime. All lies, thefts, robberies, sexual irregularities, unwarranted personal injuries to one's self or others, etc., are a departure from the demands of the moral law and are evil. In Christian ethics such violations are styled 'sin.' Violations of the laws of society or of a government are not always violations of the moral law; some of these laws are merely penal laws, and their transgression involves no moral evil.

Absolute and Relative Evil. The term 'absolute' can be taken in different meanings. Here it is taken in the sense in which it was used when speaking of 'absolute good.' An *absolute* evil, then, is the *privation of an absolute good*, and an absolute good is anything which is good for a being itself, irrespective of other beings. When a being is deprived of such an absolute good, this privation is said to be an 'absolute' evil. The two arms which man has are an absolute good for him; to be deprived of one or both, is then an absolute evil. Sight is an absolute good for a cat; to be blind, is an absolute evil for it. Life is an absolute good for every organism; death is, therefore, an absolute evil for it. A *relative* evil is the *privation of a relative good*, and a relative good is anything that is good for another. Food and drink are a relative good for man; to be deprived of sustenance is a relative evil for him. A leash on a dog is a relative evil, because it deprives him of freedom of

movement. A red-hot rod of iron, when grasped by the hand, is a relative evil, because it burns and causes pain.

Objective and Subjective Evil. An *objective* evil, as the term indicates, is the *privation of an objective good*, and the latter is anything that is good in itself, whether absolutely or relatively. Examples will be found in the preceding paragraph. A *subjective* evil is the *privation of a subjective good*, namely, the privation of the actual possession of an objective good. Thus, the loss of the possession of an automobile, of a house, of health, of sight, or of any other objective good, considered as a state or condition of the former possessor, is a subjective evil.

Real and Apparent Evil. A real evil is the *privation of a real good*, of something that is judged to be good for a being and actually is good for it. Examples are: a broken wing for a bird, disintegration for an element, vice for a human being. An *apparent* evil is the *privation of an apparent good*, the privation of something that is judged to be a real good for a being but is really not good for it. In an apparent evil, therefore, we have the privation of a real evil, since an apparent good is actually an evil; the net result is the cancellation of the evil, leaving a 'real good' in the being. Food for a critically ill patient, for instance, is an apparent good, but a real evil; to deprive such a patient of food in such circumstances, is an apparent evil,' but it is actually a 'real good.' A sharp knife as a plaything is an apparent good for an infant, though it is actually a real evil; to take this knife away from the infant, therefore, is an 'apparent evil,' but it is actually a 'real good.'

It should be fairly obvious that our judgment of evil as real or apparent, will depend upon the standpoint from which we view an evil. Depending upon the circumstances of the case, an evil may be 'real' from one standpoint and 'apparent' from another. The removal of a gangrened arm is a real evil, if we consider the loss of the arm as such; since, however, this removal may be necessary to save the life of the patient, the loss of the arm under the circumstances is more an apparent evil than a real evil. Physical suffering, taken by itself, is a real evil; but if it is the occasion of strengthening the character of the suffering person, it is rather an apparent evil.

THE EXISTENCE OF EVIL

Evil and its existence has always been a serious problem for religion and philosophy. In all ages there have been those who have asserted that evil exists as a sort of perverse positive reality. Evil, however, is a privation of some good, a 'privative nothing.' This matter must now be examined a little closer. Since all evil can be reduced to an ontological, physical, or moral evil, we can restrict ourselves to the problem of the existence of these three forms of evil.

The Existence of Ontological Evil. Can a being, *as a being*, be evil, and can ontological evil thus become a fact? This is the crux of the whole problem. A little reflection should convince us that an ontological evil in the true sense of the term cannot exist. Good is a transcendental property of all being: every being is good, and whatever is good is a being. But if every being, *as a being*, is transcendently

good, it is *ontologically* good, because then it is good precisely in so far as it is a *being*, and that is what is meant by saying that something is 'ontologically' good. If every being, however, is an ontologically good being, no being can be an ontologically evil being. Now, only a 'being' can exist; consequently, since every being is ontologically good, no ontologically evil being can exist. Hence, ontological evil (concretely, an ontologically evil being) cannot exist. It follows then, that every being, in so far as it has *any reality* at all, is good. Evil, therefore, can consist only in the privation of some reality; as such it is essentially a privative non-entity, and a non-entity, of course, is incapable of existence.

But is the above not open to a serious objection? Tuberculosis, for instance, is a disease caused by germs; these germs are, therefore, an evil. But these germs are beings. Hence, some beings are an evil. These germs exist; therefore, some evil beings exist. Certainly, the germs exist and are an evil. But are they an *evil in themselves*? Or are they an evil *for another*, e.g., for the lungs of man? In order that they be adjudged ontologically evil, it would be necessary that they be an evil in themselves. That, however, is not the case. All germs are organisms, and as such they are beings with a very definite nature of their own. Their nature is good *for the germ*; it is as good for the germs as man's nature is good for himself. Germs have their proper place in the scheme of things; their essences have their own particular purpose and end. The material of man's lungs is food for them and is a good for them. That this material happens to be taken from man's lungs, makes them an evil

for man. They are thus an evil for another (relative evil), but they are good in themselves (ontological good). The same is true of all germs, tumors, cancers, etc. As living cells they are good in themselves; relatively, of course, they may be an evil for other beings. This line of thought can be applied to anything that could possibly be conceived as an ontological evil, and it will be found that it is, for itself and in itself, ontologically good. Hence, no being can be, strictly speaking, ontologically evil.

Are not *Satan* and the *evil spirits* ontologically evil beings who actually exist? It is doubtful whether philosophy, with the use of reason alone, unaided by divine revelation, could prove their actual existence. However, accepting their existence as a fact on the authority of Christian revelation, we must remember that even Satan and the evil spirits are not entirely evil. They are created beings and, so far as their nature and essence is concerned, they were *ontologically good when created*. They did not lose this nature and essence when they sinned; they still possess the same nature and essence which they received from the hand of God in their creation. Consequently, they *still are* ontologically good in their nature and essence. Whatever evil is in them resides in their depraved will, in as much as their will is in eternal disconformity with the will of God, and that is a moral, not an ontological evil. As existing beings, therefore, even Satan and the evil spirits are not ontologically evil.

The Existence of Physical Evil. Physical evils are an established fact in the world. Many beings lack some reality which they ought to have. Sickness and injuries deprive

living beings of that physical integrity which their essence naturally demands. But it must be borne in mind that beings are physically evil only in so far as some *entity is missing* in them. Whatever entity they possess is in itself good. Thus, a tubercular lung is a physical evil only because certain portions are infected or missing; the remaining parts are good. A severed arm is a physical evil for a man, because he is now deprived of a portion of his being. But the rest of his body is not a physical evil; nor is the severed arm itself, considered from the standpoint of its constituent elements, physically evil: it is the privation of the proper relation between body and arm that is an evil, and this privation is not an entity in itself. Physical evil, therefore, consists in the *privation of being*, relative to an individual's needs, not in any positive reality as such.

The Existence of Moral Evil. That moral evils are present among men is all too evident. Sin is an undeniable fact. Grime is an everyday occurrence. But here again, it would be false to consider a moral evil as a positively existing entity. In fact, the sinful action as an action is ontologically good, because it is a being; and if the action is performed in a manner conducive to the natural purpose of the act, it is also physically good. Since, however, this ontologically and physically good act is not in accordance with the requirements of the moral law, it is morally evil. There is no morally evil *entity* here, but rather the defect or *privation of an entity*, namely, the defect of the proper relation between the act and the demands of the law. A child, for example, is playing. The mother calls the child into the house, but the child disobeys and keeps on playing. If the act of playing

was ontologically and physically good before the mother's call, it is still ontologically and physically good after the call, because the act has not changed in this respect. But the attitude of the will has changed, in as much as it is disobedient to the properly constituted authority. Nothing in the *entity* of the act has changed, but there is now a *defect of proper relation* between the entity of the act and the law which governs it; the entity as such still remains good. Moral evil, therefore, does not consist in a positive entity or reality, but in privation; whatever there is of entity in the action, is in itself good.

SOME THEORIES OF EVIL

Evil is not a primary concept; it presupposes the good as the primary concept, because evil is the privation of a good. The good must exist *first*, before there can be a privation of it; evil can only follow the good. For the same reason the presence of evil is always dependent on the presence of the good; where there is no good there can be no privation of it and therefore no evil. The good can exist without evil, but evil cannot exist without the good. First, then, was the good. Evil came later. These principles should enable us to pass a correct judgment on some theories of evil which have become prominent in the course of time.

Pessimism, as a philosophic theory, maintains that evil predominates over good, because the world at large is essentially bad. Conscious life, particularly in man, is a constant struggle, fundamentally and inescapably painful in character, so that life is not worth living and consciousness

is in itself a state of misery; the best escape from it is in unconsciousness and death. Such are the main tenets of *Buddhism* and of the modern pessimism defended by philosophers like *Schopenhauer*, *von Hartmann*, and *Nietzsche*. That pain and suffering are facts of life, no one denies; but that life, consciousness, and the world in general are intrinsically evil, cannot be admitted. Whatever is, is good; evil is only incidental to the good. That our limited knowledge cannot fathom completely the *Why* of evil is no valid argument against the essential goodness of the beings which constitute the world. When beings are limited in nature and action and are mutually dependent on each other for the full actualization of their inherent reality, it is inevitable that the gain of one involves loss for another. Evil is thus relative, not absolute; the scheme of things as a whole is harmonious and ontologically good.

Excessive Dualism is another false theory. In this view all the good present in the world is due to a supreme Principle of Good, and all the evil to a supreme Principle of Evil. These two principles are independent of each other and are usually conceived as being co-equal, co-extensive, and co-eternal. Such is the theory of *Zoroastrianism*. According to *Zoroaster* (or Zarathustra), a Persian philosophic religious reformer who lived in the seventh or sixth century B.C., the forces of good and evil are waging a constant battle for supremacy in the universe. The supreme Principle of Good is Ahura-mazda (Ormuzd), and the Supreme Principle of Evil is Anra-mainyu (Ahriman); the former is the source of all good in the world, and the latter the source of all evil. In the third century A.D., *Manes* introduced this doctrine and

founded the sect of *Manicheism*. God is the supreme Principle of Good, and 'matter' the Principle of Evil. His interpretation of 'matter' as the Principle of Evil harks back to the doctrines of some of the earlier Greek philosophers. In every theory of excessive dualism the Principle of Evil is *conceived as a positive being*, either conscious or unconscious. This, of course, is an erroneous conception, because evil is a privation of being, not a positive reality; it cannot be present except in so far as it is a privative defect affecting some ontological good. Besides, we know, from what has been said before, that every existent being is an ontological good in its nature and essence. Consequently, also this supreme Principle of Evil must be ontologically good, because it possesses a nature or essence; as such it must derive its ontological goodness from the supreme Principle of Good; in that case, however, it cannot be co-equal and co-eternal with the Principle of Good, but must be dependent on the latter. The Principle of Evil, therefore, is contradictory in its very concept.

Summing up our investigation of the transcendental properties of being in general, we arrive at the following results: Being, one, true, and good are convertible ideas. Every 'being' is one, true, and good. Every 'one' is being, true, and good. Every 'true' is being, one, and good. Every 'good' is being, one, and true. These realities are inter-identical; they include each other implicitly. Between them there exists only a virtual distinction with an imperfect foundation in the thing.

SUMMARY OF CHAPTER XIV

Goodness, like unity and truth, is a transcendental attribute of being.

1. *The Concept of Goodness.* Good is what all desire. Something is good in so far as it is suitable to a natural tendency or appetency. The 'good' can be defined as any reality which suits the nature of the being which strives for it.

2. *Divisions of Goodness.* The following are typical divisions of the good, viewed from different standpoints:

- *Ontological, Physical, and Moral Good.* Something is an *ontological* good, when it is a good in its very entity or reality. It is a *physical* good, when it satisfies the demand of the nature of a being. It is a *moral* good, when it has everything demanded of it by the moral law.
- *Absolute and Relative Good.* An absolute good is anything which is good for a being itself, irrespective of other beings. A relative good is anything which is suitable to another.
- *Objective and Subjective Good.* An *objective* good is anything that is good in itself. A *subjective* good is the actual possession of an objective good.
- *Real and Apparent Good.* It is *real*, when it is judged to be good for a being, and it actually is good for it. It is apparent when it is judged to be good for a being, but it is actually not good for it.

- *Disinterested, Delectable, and Useful Good.* A *disinterested* good is any good considered merely as giving perfection. A delectable good is a relative good which gives pleasure to another. A *useful* good is a relative good which is desired as a means to acquire perfection or pleasure.

3. *The Convertibility of Being and Goodness.* Every being is good, and whatever is good is a being. Every being is in some way perfect, because every actuality is a certain perfection. But what is perfect, even in a limited way, is appetible and therefore good. Whatever is good is also a being; this is clear from the fact that it cannot be 'nothing,' since 'nothing' is not suitable to anything.

4. *The Concept of Evil.* Evil is the absence of a reality which ought to be present; it is the privation of a required good.

5. *Kinds of Evil.* There are as many kinds of evil as there are kinds of good. In each case the evil will be the privation of the respective kind of good. For example, an *ontological* evil is the privation of an ontological good, a real evil is the privation of a real good, etc.

6. *The Existence of Evil.* Evil is not a positive reality; it is the *privation* of a required good and as such a privative nonentity. Pessimism, which considers all things as essentially evil, is therefore false. So, too, are Zoroastrianism and Manicheism, since they maintain the existence of a supreme Principle of Good and a supreme Principle of Evil.

Chapter 15

BEING AND BEAUTY

BEAUTY IS A MOST ELUSIVE QUALITY. ITS NATURE IS SO TENUOUS that it always seems to escape in the very moment of its capture. There is hardly a term in any language which is used more and abused more than 'beauty.' The conflicting varieties of its definition are truly amazing — a sure indication of the complexity of its nature and of the many-sided character of its appeal. Beauty manifests itself in so many and in such divergent forms that it is extremely difficult to discover the general element common to them all.

The concept of the beautiful is closely related to the concepts of unity, truth, and goodness, the transcendental attributes of being; it is even considered by some philosophers to be a transcendental or quasi-transcendental property. Like all fundamental and primary ideas, it is more easily recognized in a concrete experience than abstractly defined in words. The best method of acquiring a serviceable knowledge of the beautiful will be to analyze our experience of the beautiful and thus gradually enucleate a more formal definition.

OUR EXPERIENCE OF BEAUTY

Beauty pleases. Universal experience and judgment show this. We do not consider that to be beautiful which displeases and annoys us, at least not under this particular aspect of being 'beautiful.' Whatever is beautiful, whether it be a poem, a painting, a melody, a piece of sculpture, or an architectural structure, is always considered to be such that it pleases, gratifies, and gives enjoyment.

Beauty gives *disinterested* pleasure. The pleasure derived from beauty is styled 'aesthetic pleasure.' We do not consider our pleasure to be aesthetic when our main concern on seeing an apple is to eat it; this is a selfish food-pleasure, and it is not founded on the beauty of the apple. We experience aesthetic pleasure, when we derive pleasure from *beholding* it. If a man owns a painting and takes pleasure in it because he knows he can sell it at an advantage, he is not said to have aesthetic pleasure; but if he is satisfied to *contemplate* it and thus enjoy it, then he is enthralled with its beauty. There is beauty in the seas, in the stars, in the sunrise, in the waterfalls, in the mountains; but there is no selfish enjoyment in these things. The agreeable and pleasurable feelings engendered in us through the mere possession of an object or through the satisfaction of the lower sentient appetites, are not aesthetic, for they are too *organic* and *selfish*. Things may taste and smell and feel 'agreeable,' but such pleasure is not the delight encountered in the enjoyment of the beautiful.

The *primary object*, therefore, of desire in beauty is not the pleasure derived from profit, consumption, possession,

or even use, but the pleasure aroused through the *contemplation* of the beautiful. Hence, the *ear*, the *eye*, and the *imagination* are the sense faculties properly engaged in the production of aesthetic delight, and they are mainly perceptive in character.

Beauty gives disinterested *intellectual* pleasure. The intellect is necessary for the enjoyment of beauty. Man is the only animal which appreciates beauty. Brutes do not contemplate the beauty of the flowers, the hills, the woods, the sunsets, etc., nor do they manifest anything of the joy that we feel in the contemplation of these things. They remain indifferent in the presence of all the beauty of nature and are concerned with beautiful objects only in so far as they are of assistance to them in the struggle for existence. The reason why brutes cannot enjoy beauty in any true sense is plain: *order, proportion, unity, appropriateness, the agreement between the ideal and the real*, are fundamental elements of beauty, and the knowledge of these elements rests upon a more or less conscious comparison of the parts in themselves and with the idea expressed in the whole. This, however, is a matter of rational judgment, and an intellectual being alone has the faculty for this. Beauty, therefore, must have an intelligible content.

Beauty gives a disinterested *intellectual-sensuous* pleasure. The intellect is necessary for the perception of the beautiful, because beauty has an intelligible content. But the intellect perceives it through the mediation of the senses. The intelligible, supra-sensible quality or 'idea' must be perceived in a *sensibly pleasing appearance* in order to

be beautiful. It is a universal demand that the artist pleasantly impress the senses with images and plastic forms. Naked thoughts leave us cold. Ideas alone, free from the beauty of form, are found in science, mathematics, and philosophy; but no one looks upon these as being the proper medium and vehicle of beauty. We go to art and to the artist for beauty and its enjoyment. Hence, the idea, or truth, alone does not suffice to make a thing beautiful; the idea, or truth, must be embodied in a sensibly pleasing form before we can consider it beautiful. The scientist, the mathematician, and the philosopher may present the idea, or truth, in a far clearer and more convincing manner than the artist; they enlighten, but they do not, strictly speaking, give us aesthetic delight. The artist may express the same idea, or truth, less exactly, but he clothes it in form and figure; and we are impressed, animated, delighted, pleased.

The reason is this: Like pleases like, *simile simili gaudet*. As we are one in essence, consisting of mind and body, so the beautiful is one in nature, consisting of *idea* and *form*. The way of art is therefore twofold: the idea may be first and then the form, or the form may be first and then the idea: true idealism and sound realism, the idealized real and the realized ideal. It is the happy combination and fusion of idea and form which constitutes beauty, corresponding to the composite nature of man. Consequently, there must be an *equilibrium* established between the *intellectual* and *sensible* elements. An overcharge of idea or a lack of form would mean a lack of beauty, abstractness, too much intellectuality; an

overcharge of form or lack of idea would mean shallowness and extravagance.

Beauty gives a disinterested intellectual-sensuous pleasure due to the *radiant perfection of a thing*. Most philosophers acknowledge that beauty is not purely subjective in character, but that it has its foundation in the things themselves and that we experience the delight of beauty in consequence of some objective factors present in the objects.

Beauty is not mere appropriateness. The arrangements of a barn may be very appropriate, but the ordinary barn can hardly be said to be beautiful. Nor is beauty the inner perfection of a thing, considered as such. Many ugly things are intrinsically perfect, for instance, the caw of a crow, the bray of a mule, a toad, a factory, a three-legged stool; but these are seldom considered to be beautiful.

Beauty is the *perfection* of a thing manifested in a *pleasing, happy manner*. Just as light, splendor, radiance, and color produce a pleasing impression on the eye, so also we call beauty in general 'resplendent, radiant perfection.' That perfection and goodness are fundamental properties of beauty, is shown by the fact that beauty pleases. Now, something that pleases is desirable, and the desirable is, as such, good.

Beauty gives a disinterested intellectual-sensuous pleasure due to the radiant perfection of a thing, primarily in so far as it exerts an *appeal to our cognitive faculties* and not to our will. Order, harmony, rhythm, unity amid variety, etc., are essential elements of beauty, and their appeal is evidently to the *perceptive* powers of the mind. Experience

proves this. Things like a colorful landscape, a symphony of Grieg, a poem of Francis Thompson, a drama of Shakespeare, a Madonna of Raphael, a cathedral of Rheims, or a statue of Praxiteles, produce in us primarily a satisfaction of intellect and imagination. Their apprehension and appreciation afford us the pleasure peculiar to beauty; but apprehension and appreciation are acts of the cognitive faculties, not of sense-appetency or will.

It is only after we have apprehended and appreciated the inherent beauty of something, that aesthetic pleasure follows as a natural result.

St. Thomas Aquinas furnishes us with a succinct elucidation of these points. "Since that is good which all desire, it belongs to the concept of the good that the appetency come to rest in it. But it pertains to the concept of the beautiful that the appetency come to rest in its contemplation or knowledge (*in ejus aspectu seu cognitione*). Whence it happens that those senses are primarily concerned with the beautiful which are mostly cognitive in character, namely, sight and hearing in the service of the mind; for we speak of beautiful sights and beautiful sounds. Concerning the objects of the other senses, we do not use the term 'beautiful'; for we do not speak of beautiful tastes or odors. And thus it is clear that the beautiful adds to the good the relation of the cognitive faculty, so that we call that good which directly agrees with the appetitive faculty, and beautiful that whose apprehension pleases."¹ He summarizes the beautiful in the following terse expression:

*"Things are beautiful which please when seen."*² The context shows that by 'seen' he meant as much as 'known, apprehended, imagined, perceived, contemplated': which agrees with our contention that beauty appeals primarily to our perceptive powers and not to our sense-appetency and will.

If we now analyze the data of our experience, we perceive that whatever is 'beautiful' possesses certain objective elements.

OBJECTIVE ELEMENTS OF BEAUTY

By the objective elements of beauty we understand those *elements or factors in the object itself* which enable us to recognize the object as 'beautiful.' Some of these factors are more general and others are more particular. The *general elements* of beauty agree to a great extent with the transcendental attributes of unity, truth, and goodness; but not altogether. There is a close relation between *beauty and unity*. Unity amid complexity is a perfection and aids the intellect in grasping the underlying meaning of things without distracting its attention and weakening its vigor of activity. The grace of line in an Apollo Belvidere, the magnificence of St. Peter's in Rome, the charm of a Bach minuet, the grandeur of Michelangelo's *Last Judgment*, the glory of Homer's *Iliad* — is not a goodly amount of their imperishable beauty due to the proportion, the harmony, the rhythm, the symmetry of their manifold and intricate details? But to admit this is to admit that beauty is intimately connected with 'unity.'

Beauty, however, implies more than mere unity. We find unity also in a mathematical theorem, in a scientific deduction, in a philosophic syllogism, and in a mechanical contrivance; but these are not necessarily beautiful on that account. We may acknowledge their unity and still not experience any delight in their knowledge. It takes more than unity to make a thing beautiful.

There is also a close relation between *beauty and truth*. The appeal of beauty, as just shown, is mainly to the perceptive powers, and especially to the intellect. The fact that animals show no appreciation of beauty in the strict sense, is alone sufficient to prove this. All beauty possesses an *intelligible* quality which transcends the ordinary realm of sense-perception. It is not sufficient to 'perceive' beauty; beauty must also be 'apprehended' and 'understood' in order to be appreciated. This shows that there is an element of truth in everything beautiful.

Again, however, beauty must not be identified in every respect with the true. Truth as such merely commands our assent, but it does not necessarily afford us aesthetic delight. In many instances truth may even displease, annoy, and pain. The truth of statistical facts is aesthetically barren. The truth of a chemical analysis leaves us cold. The truth of an algebraic calculation is devoid of the emotional response associated with the contemplation of beauty. Truth as such is not beauty.

Similarly, there is a close relation between *beauty and goodness*. Beauty satisfies, pleases, delights; and satisfaction, pleasure, and delight have a natural reference to an appetency, because an object which has these

characteristics is a delectable good. Such emotional releases are, of course, a subjective element in the enjoyment of the beautiful, but they are elicited by the object itself when contemplated by the observer. The element of goodness, therefore, is also present in the beautiful.

On the other hand, there is a difference between beauty and goodness. The good satisfies the appetency directly, as something to be acquired, possessed, and retained, not because it is known and perceived. Beauty, however, is the good in so far as it delights the beholder through its perception and contemplation. The good is always something suitable to a striving power, and for that reason it is desired by an appetency; an appetency, therefore, is somewhat selfish in its trend. But beauty gives satisfaction and pleasure through the simple contemplation of it, without the presence of any acquisitive tendency. One can be thrilled while listening to a selection by Kreisler or Paderewski, and never desire either their gifts or their instruments of music.

The general elements of unity, truth, and goodness are thus seen to be present in the beautiful; but beauty is not a transcendental attribute of being, so that every being would of necessity also be beautiful. *Being and beauty are not convertible concepts*, like being and unity, being and truth, being and goodness. Everything beautiful is a being, but the converse statement is not true. While these concepts are undoubtedly closely related, they are not identifiable: there is a difference between beauty and unity, truth, and goodness.

TURNING NOW TO THE *PARTICULAR ELEMENTS* OR FACTORS OF beauty, we find that a number of properties must be present in an object in order that it may be styled 'beautiful.' Beauty elicits joy and delight in the beholder, and these emotions are the concomitant result of the normal, healthy, full, vigorous exercise of any faculty. The joy and delight engendered by the beautiful will, therefore, be supreme when all the faculties involved in the contemplation and appreciation of the beautiful are aroused to such an exercise of their powers. Three fundamental properties are required for this.

Integrity or completeness is the first. Any noticeable defect or mutilation in a thing makes an unpleasant impression on the beholder. The mind is dissatisfied with this incomplete condition and makes an effort to restore the missing part in its imagination; this effort disturbs its poise and hinders it from coming to a proper state of rest and calm in its contemplation. As a result of this mental disturbance the aesthetic enjoyment is marred by a certain amount of annoyance and irritation. We observe this when contemplating a dilapidated building, a damaged painting, a crippled body, an awkward dance; or when listening to a melody out of tune and to the badly memorized lines of a drama; or when reading the poorly constructed verses of a mediocre poet. Of course, in some instances the defects may be so completely overshadowed by the resplendent beauty of the object as a whole, that small mutilations or blemishes escape our notice almost entirely; in that case we

would experience the full enjoyment of beauty by simply concentrating our attention on the object as a whole. But defects, as defects, detract from the beauty of an object; and if these defects force themselves constantly on our attention, the object cannot be said to be really beautiful.

Proportion or balance is another requisite. It is the index of a mind which works in an orderly fashion. Just as the mind experiences pleasure in evolving order out of confusion, so it also experiences aesthetic pleasure in detecting an orderly arrangement in what at first seems to be chaotic confusion. A mere jumble does not please. A heap of stones is not an aesthetic object; but if they are arranged in the orderly construction of a building, provided there be symmetry and balance in the arrangement, they form an object of beauty. An orchestra tuning its instruments is a mere confusion of irritating noises; but when the instruments weave the same sounds into the intricate harmony of an operatic overture, we have beauty of a high order. Irregular daubs of paint are unaesthetic; when these colors, however, are applied by an artist to a canvas, they become an immortal masterpiece of exquisite beauty. The secret is proportion, balance, harmony, symmetry — in a word, *unity amid variety*. Unity without variety is not beautiful, because in that case the energy of the perceptive faculty will be exercised in an unbroken, unrelieved strain; and that would produce tension and fatigue, but not pleasure. Variety without unity is not beautiful, because then the mind's energy would be scattered and spent without being able to come to rest; and that would disturb and hinder the normal, healthy, full,

vigorous activity of the faculties. Unity amid variety acts like a focus, concentrating the attention along certain definite lines, bringing harmony into the manifold elements and making of them a simplified whole; this facilitates the mind's activity, gives it a feeling of restful completeness, and thereby produces in it the joy and delight so characteristic of beauty.

Clarity or splendor is the third requirement. To be beautiful, an object must have a certain amount of compelling force; it must be impressive; it must possess a vivid presentation; it must attract and charm through its very appearance. Only then will it be able to call forth a vigorous activity on the part of the contemplating person. The elements of beauty may not be obscure or hidden, otherwise they will demand undue labor and effort of the mind to discover them; and that would beget strain and pain, not joy and delight. Joy and delight must be spontaneous, must spring up in the heart like a fountain and overflow into the emotions; and that will be the case only when the clarity of beauty exercises the perceptive faculties in such a way that they function with ease and liveliness. That is why all the arts use contrast as an effective technique to set the splendor of beauty in a sharper light; the elements of aesthetic value then fairly leap into the central position of attention and thereby give the mind the proper perspective which enables it to survey the parts and the whole in a comprehensive glance.

Such, it would seem, are the main objective elements present in objects which are called 'beautiful.' Many individual quantities have been pointed out and analyzed in

the various kinds of natural and artistic beauty; upon examination, however, they all appear to be reducible to these fundamental attributes and qualities. In some forms of beauty the one or the other attribute or quality is embodied in a predominant manner, but every form of beauty contains them all in some measure. Beauty, of course, never appears in absolute purity, for the simple reason that no finite thing is perfect. There will always be an over-stressing or under-stressing of some particular element, so that it is next to impossible to find any object which is altogether beautiful.

THE DEFINITION OF BEAUTY

To define beauty adequately is a most difficult task. Beauty manifests itself in such a multitudinous variety of forms, that an enucleation of its fundamental and essential character is well-nigh impossible. The history of aesthetics proves this. From Socrates to the present day beauty has been the subject of analysis and discussion. Never, however, has any philosopher, scientist, or artist been able to formulate a definition of beauty capable of satisfying everybody. The definitions range all the way from expressions of the crudest naturalism to those of the loftiest idealism.

How, then, shall we define beauty? From what has been said, we venture to propose the following definition: *Beauty is a blending of the unity, truth, and goodness in a thing, characterized by completeness, proportion, and clarity of presentation in an intellectual-sensuous form, so as to*

produce a disinterested emotional pleasure in a rational perceiver. If this definition seems complicated, it at least attempts to do justice to the subjective and objective elements involved in the perception of beauty.

This definition, of course, views beauty from the standpoint of *man's* nature. The reason is obvious. The beauty which we know is the beauty which appeals to us, and we are human beings consisting of body and soul, animality and rationality. The nature of beauty *for us* must, therefore, partake of the nature of man: it must be intellectual and sensuous, the embodiment of an intelligible *idea* in a material *form*. Its appeal must be an appeal to the whole man in his composite nature, not merely to the one or the other side of his being. What the objective elements of beauty would be for a pure spirit or for God, we have no way of knowing. No doubt, they will be purely spiritual in character. God must be infinite, transcendent, absolute Beauty. For spiritual beings beauty consists perhaps in the full agreement of reality with its thought-ideal.

Will the definition of beauty given above enable us to point to a particular object and immediately recognize it as beautiful or not beautiful? Hardly. The reason for this distressing deficiency in every definition of beauty lies in the fact that we first intuitively feel something to be beautiful and only then attempt to discover the elements which make it beautiful. Aesthetic pleasure as a sensation is an *ultimate psychological experience incapable of complete analysis*. It is found to be present, and must be accounted for. The enjoyment of beauty is as much a subjective affair as it is objective. It is precisely in the subjective field of

man's emotions that so much diversity occurs, due to differences of individual temperament, educational standards, and cultural environment. This accounts for the extreme fluctuations of opinion regarding beauty in general and beautiful things in particular, and this condition finds expression in the oft-repeated phrase: There is no accounting for tastes, *de gustibus non est disputandum*.

Nevertheless, the definition may be of service in acquiring a fuller understanding and a deeper appreciation of beautiful things when we experience the aesthetic pleasure which accompanies the contemplation of beauty. Perhaps St. Thomas' definition of the beautiful is after all the best: *Pulchra sunt quae visa placent*, 'things are beautiful which please when perceived.'

SUMMARY OF CHAPTER XV

Beauty is an elusive quality of things. Our experience of beauty must guide us in acquiring a proper conception of beauty.

1. *Our Experience of Beauty.* Beauty, as experience shows, gives a disinterested intellectual-sensuous pleasure due to the radiant perfection of a thing, primarily in so far as it exerts an appeal to our cognitive faculties and not to our appetitive faculties. “Things are beautiful which please when seen.

2. *Objective Elements of Beauty.* There are general and particular elements present in things called beautiful. The general elements are unity, truth, and goodness. Beauty, however, does not coincide completely with these transcendental attributes of being. Being and beauty are not convertible ideas. The *particular* elements of beauty are integrity or completeness, proportion or balance, clarity or splendor.

3. *The Definition of Beauty.* From the above, beauty can be defined as a blending of the unity, truth, and goodness in a thing, characterized by completeness, proportion, and clarity of presentation in an intellectual- sensuous form, so as to produce a disinterested emotional pleasure in a rational perceiver. Perhaps the definition of St. Thomas Aquinas is after all the best: “Things are beautiful which please when perceived (seen).”

PART III

THE SUPREME CATEGORIES

Chapter 16

THE CATEGORIES

ONTOLOGY TREATS OF BEING IN ITS MOST GENERAL ASPECTS. The various particular kinds of beings belong primarily to the special sciences; they are considered by ontology only in so far as they exhibit characteristics which pertain to being in general.

The first part of our investigation examined being and its primary determinations. This included an elucidation of the concept of being, the contraction of being to its inferiors, the supreme principles based on the concept of being, act and potency, change and the principle of change, and essence and existence. The second part treated of the transcendental attributes of being which are always present whenever being is present. These are the attributes of unity, truth, and goodness. Though different in concept from being as such, they are in reality identical with it.

In this third and last part of ontology we must investigate the different modes in which real being is found to be actualized and determined in nature. Since, however, philosophy is interested only in the 'ultimate' reasons, causes, and principles of things, ontology seeks to know the

ultimate and *supreme modes of being*. This leads us to a consideration of the *categories or predicaments*.

THE CONCEPT OF THE CATEGORY

Aristotle coined the term 'category,' as it now is used in metaphysics. Originally, the term had application only in a court of law or in a forum (Gr., *κατηγορεῖν*, to accuse, charge, demonstrate, attribute; *κατηγορία*, accusation, attribution), and referred to the accusation or charge lodged against someone in a judicial tribunal. In making a charge, something is always attributed to the accused. Aristotle perceived a similarity between a court of law in its verdict and the mind in its act of judgment ('judgment,' as will be observed, is also a forensic term), in as much as the mind in its judging attributes something (the predicate) to another (the subject). The mind acts like a judge and passes judgment on the matter under consideration. Thus, when the mind states that 'Man is a rational animal,' it attributes the predicate 'rational animal' to the subject 'man,' and the result is a judgment and sentence. Due to this similarity of attribution in the judgment of the court and in the judgment of the mind, Aristotle transferred the term 'category' to philosophy and gave it a logical meaning, namely, the *logical attribution* of a predicate to a subject. In a technical and philosophic sense, then, Aristotle understood the categories to be *the supreme and ultimate genera or classes of predicates*, as found in our judgments and sentences. The philosopher Boethius translated the Greek term into the Latin *praedicamentum*, from which we

derive the English term *predicament*. The term 'predicament' does not, of course, mean anything like a perplexing or embarrassing situation; it is used here in the technical meaning of a 'class of predicates.' 'Predicament' and 'category' are synonymous terms.

It will be noted that Aristotle employed the term 'category' or 'predicament' primarily in a *logical* sense, as a classification of the predicates used in our judgments. In as much as the predicates are direct, universal ideas applied to individual subjects, he considered the categories or predicaments to be the ultimate and supreme classes or groups of direct universal ideas. Taken in this sense, the categories belong to logic.¹ Aristotle, however, did not restrict the meaning of 'category' to this logical sense; he also used the term in an *ontological* sense, and that with just reason. Ideas stand for things, objects, beings; an idea is the intellectual representation of a thing. And that is also true of judgments; judgments represent facts about things. Ideas and judgments express *reality*. When we say that 'Air is transparent,' we do not merely wish to state that the idea 'transparent' is a predicate which the mind in its judgment attributes to the idea 'air' as a subject; we mean to state that 'transparency' is a physical quality which belongs in reality to the physical substance 'air' as it exists in nature, independent of the ideas and judgments of our mind. Ideas and judgments thus express things and facts about things.

Since our universal ideas represent real beings, the categories must be classifications of real beings just as well as they are classifications of universal ideas. Besides the *logical* meaning, we thus have also the *ontological* meaning

of categories or predicaments: they are not only the ultimate and supreme classes of *predicates*, but also the ultimate and supreme classes of *beings*. And since 'being' is the proper subject matter of ontology, the categories must receive special treatment in this department of philosophy. From an ontological or metaphysical standpoint, then, the *categories or predicaments* are defined as the *ultimate and supreme modes of real being*. These modes are expressed in the predicates of our judgments, and these predicates attribute various 'modes of reality' to the things designated by the subjects; in this manner our judgments are an interpretation of reality and form the basis of true knowledge.

Consider, for instance, judgments like the following: 'This man is a *substance*; he is *white*; he is *five feet and eight inches tall*; he is the *father* of a two-year-old son; he *works* hard; he has been *injured*; he lives in *Chicago*; he was born in *A.D. 1900*; he owns a *beautiful home*.' Each one of these predicates expresses a mode of being or reality as it is found in this individual and gives us information about him. The items of information which could be predicated of an individual are incapable of complete enumeration, because they change and multiply from moment to moment. Something could be said about every single portion of his being during every single moment of his existence. The result would be a total confusion of ideas, unless order can be brought into this itemized information. To reduce this chaotic multiplicity of ideas about a thing to *order and system*, is the purpose of the categories. At the same time, the categories will arrange the manifold *modes of reality*,

which determine a being, into the order and system of a few *supreme classes*, so that our mind is able to survey all reality from a few general viewpoints. This systematization and classification of real being will be a great aid to understanding and interpreting the things of this world.

This leads us naturally to the question: How many categories are there? Or, to put it in a different way: What are the supreme classes or modes of real being?

THE PRINCIPLE OF THE CATEGORIES

Since it is the purpose of the categories or predicaments to bring order and system into our knowledge of reality as experience it in and around us, the number of categories should *be neither too small nor too large*. If too small, the categories would give us little aid in clarifying our knowledge, since too many divergent kinds of reality would be grouped under a single class. If too large, the categories would defeat their purpose, because the mind would be confused in contemplating a multitude of classes. Whatever the number, it should not be arbitrary, but natural, i.e., based on the things themselves as they are found in nature; the categories must be *natural divisions of the modes of being*, the result of observation and experience. Again, the categories must contain a *complete classification* of being. Every being and every determination of being must be reducible to the categories; they would fail in their function if any real being or mode of being would find no place in the system. Such are the requisites of a truly serviceable list of categories. Of course, if the nature of real being, as actually

found in the world, would lead us to a very small or a very large number of categories, we could do nothing but accept them; in that case, however, we could derive little benefit from them.

The categories, then, possess a double purpose and function: the ultimate division and classification of our 'ideas,' and the ultimate division and classification of the 'modes of being.' This double purpose and function of the categories will show us the *principle of division* according to which we can arrive at the proper number of categories. Now, 'being' and its 'modes' can be found only in individual beings, since only individual beings can have actual existence. *Individual being*, therefore, is the basis and principle of all predication in our judgments; and it must, for that reason, also be the basis and *principle for the division* and number of the categories.

Because of this close connection between the different kinds of predicates and the different modes of being, the most natural method of discovering the proper number and order of categories will be to investigate the *fundamental questions* which can be asked about an individual being. The answers to these questions will give us the ultimate classes of predicates attributable to the subject, and these predicates will in turn give us the ultimate modes of being according to which the individual being is determined and actualized in nature. In this manner we arrive at the *ontological categories*.

The categories are a challenge to the ingenuity and resourcefulness of the philosopher. Aside from the fact that a list of categories is a working necessity for science and

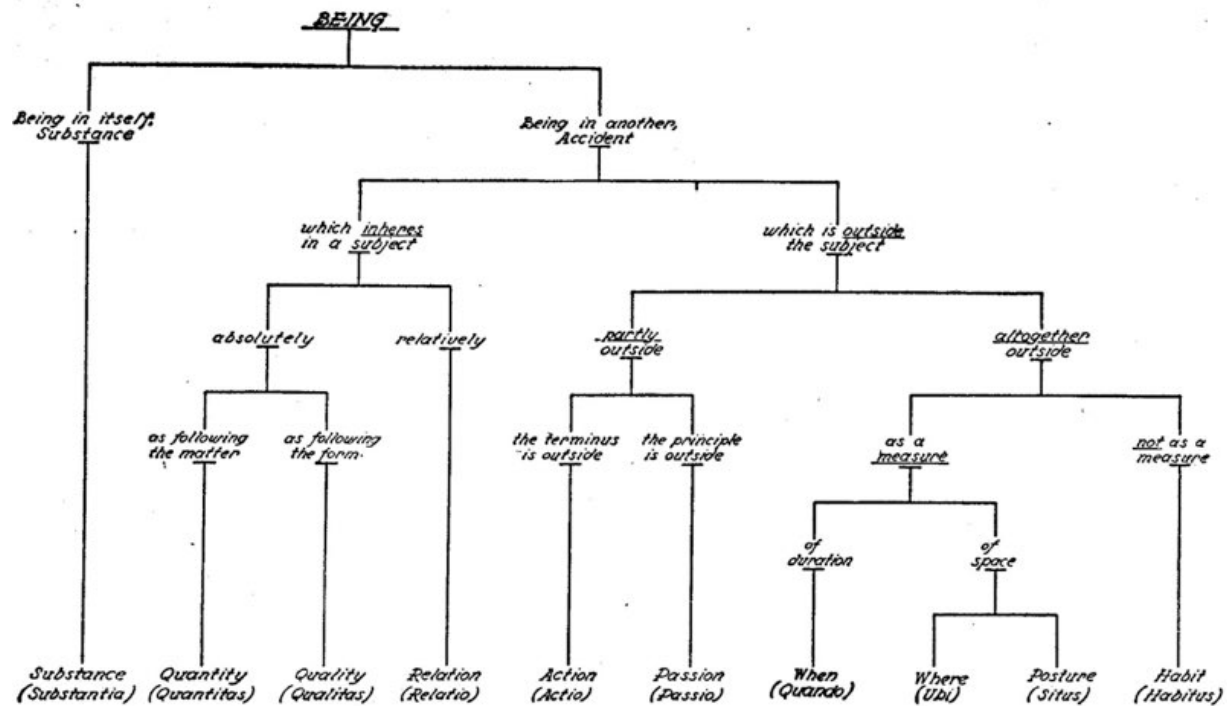

philosophy, the very difficulties involved in such a selective list have been a constant spur to the philosophers to devise a system of categories which will be both serviceable and correct.

THE CATEGORIES OF ARISTOTLE

Before the time of Aristotle, the problem of a list of categories does not seem to have occurred to the minds of the early philosophers. We find certain classifications of things, but they hardly deserve the name of 'categories.' Perhaps the closest approach to anything resembling the categories, as we understand them, was made by the Hindu philosopher *Kandda* (sixth century B.C.). He enumerates six classes of existence: substance, quality, action, genus, individuality, and concretion or co-inherence. The crudeness of this list is apparent. The *Pythagoreans* (sixth century B.C.) had a list of ten classes of opposites: light and darkness, one and many, good and evil, rest and movement, masculine and feminine, right and left, finite and infinite, even and odd, straight and curved, square and oblong. Plato made no attempt at an enumeration of categories, although he seems to divide all things into being, rest and motion, same and other.

The genius of *Aristotle* (384—322 B.C.) attacked the problem in a definite manner. He distinguishes ten distinct categories: substance (οὐσία) and nine accidents (συμβεβηκότα). The nine accidents are: quantity (ποσόν), quality (ποιόν), relation (πρός τι), action (ποιεῖν), passion or reaction (πάσχειν), where or place (πού), when or time

(ποφῆ), posture (κεῖσθαι), habitus or external condition or state (ἔχειν). In the fourth chapter of his *Organon*, Aristotle enumerates them as follows: “Of things incomplex enunciated, each signifies either substance or quantity or quality or relation or where or when or position (posture) or possession (habitus) or action or passion. But substance is to speak generally, as ‘man,’ ‘horse’; quantity, as ‘two’ or ‘three cubits’; quality, as ‘white’; relation, as ‘greater’; where, as ‘in the forum’; when, as ‘yesterday’; position, as ‘he sits’; possession, as ‘he is shod’; action, as ‘he cuts’; passion, as ‘he burns.’ Each of these ten categories expresses an attribute that can be predicated of a subject, and as such also represents some distinct mode of being which can be found in an individual. Each category is an answer to a question that can be asked about a thing. In order to understand properly this list of supreme modes of being, a brief explanation of the single categories may not be amiss.

Substance is any being which exists in itself, needing no other as a subject in which to exist. Examples: man, lion, tree, stone. It is the answer to the question: 'Who or what is this thing?' For instance: 'The oak is a plant; iron is a metal.'

Quantity is an attribute of the material (determinable) element in a being; extension, number. Examples: weight, size. It is an answer to the question: 'How big or how much is it?' For instance: 'The pole is ten feet long; it weighs one hundred pounds.'

Quality is an attribute of the formal (determining) element in a being. Examples: intelligence, strength, health, warmth, color, faculties of body and mind. It is an answer to the question: 'What sort of thing is it?' For instance: 'The rose is *red*; man is *intelligent*.'

Relation is the bearing of one being to another, a bond connecting concepts or things. Examples: paternity, equality, superiority, likeness. It is an answer to the question: 'To what or whom does it refer?' For instance: 'He is *older*, or younger, than __; the two are *equals*.'

Action is the production of an effect in another; it is expressed by the active, transitive verb. Examples: painting, baking, shooting, sawing. It is an answer to the question: 'What does it do?' For instance: 'The dog is *gnawing* a bone; the man *drives* his car.'

Passion (reaction) is the reception of an effect from another, in the sense of 'bearing, enduring, suffering, receiving, being acted on'; it is expressed by the passive voice of the transitive verb. Examples: being heated, being killed. It is an answer to the question: 'What is happening to it?' For instance: 'The anchor is *dropped*; the man is *shot*.'

When is situation in time. Examples: today, tomorrow, soon, in the beginning. It is an answer to the question: 'When, at what point of time?' For instance: 'He was there last year; the ship is docking *now*; the train will arrive in *five minutes*.'

Where is position in space. Examples: upstairs, in the country, on the table, at home. It is an answer to the question: 'Where is it?' For instance: 'He is downtown; he lives in *New York*; the book is on the *shelf*.'

Posture is the disposition of parts among themselves, in the sense of 'attitude'; immanent or intransitive action expressed by an intransitive verb. Examples: walking, sitting, upright, standing, sideways, flat. It is an answer to the question: 'In what attitude?' For instance: 'The tower is

leaning; the dog is *running*; the tree lies *prone* on the ground.'

Habitus is the condition resulting from clothing, equipment, physical adjuncts; or a condition or state, expressed by the reflexive verb. Examples: clothed, shod, hatted; praising one's self, hurting one's self. It is an answer to the question: 'How surrounded, equipped; how conditioned?' For instance: 'He *wears* gloves; he is *disgusted* with himself.'

IN SURVEYING THIS LIST, IT IS BUT NATURAL TO ASK WHAT *LINE OF reasoning* Aristotle used so as to arrive at this particular number. We do not know. Nowhere in his writings does he explain his method of selection. Again, *must* there be just *ten* categories? Aristotle himself at times omits one or the other from his enumeration.² He gives the impression that he was not always sure in his own mind as to the necessity of this exact number. Eventually, however, he seems to have settled definitely on the list as given previously. Since Aristotle does not give us his reasons for this classification of the supreme categories, other philosophers have attempted to show that they are *grounded in nature* and have a foundation in things as we experience them; they have, then, objective value and are not the result of an arbitrary arrangement or of an *a priori* deduction. St. Thomas Aquinas offers the following explanation³ for the Aristotelian categories:

Being either exists in itself, without inhering in a subject, and then it is substance; or being merely affects and

modifies a substance, and then it is an *accident*. Accidents modify a substance intrinsically or extrinsically. Among those accidents which affect a substance 'intrinsically,' some may inhere in the substance relatively, and then we have *relation*. Others may inhere in the substance absolutely; if such an absolute accident follows the matter of the physical substance, we have *quantity*, and if it follows the form, we have *quality*. Among those accidents which affect a substance 'extrinsically,' some are partly extrinsic and others are altogether extrinsic. Among the 'partly extrinsic' modifications, the term of activity may be outside the substance, with the principle of activity within the substance, and then we have *action*; or the principle of activity may be outside, with the term of activity within the substance, and then we have *passion* or reaction. Among those accidents which are 'altogether extrinsic' modifications, some will affect the substance as a measure of its duration, and then we have *time*; or they will affect it as a measure of its place in space or as a measure of the disposition of its parts relative to themselves and to space, and then have either place or posture. Other 'altogether extrinsic' modifications are not a measure of the substance at all, but merely affect it as belonging to its surroundings and conditions, and then we have *habitus*. The diagram on [previously] gives a schematic arrangement according to the ideas of St. Thomas.

This searching analysis shows that Aristotle was justified in drawing up his list of ten categories. They flow naturally from the very concept of being. The number is neither too small nor too large; and the compactness and complexity,

the unity and flexibility of the list is such that it is serviceable for all practical purposes. It establishes order in our knowledge, by giving us a systematization and classification of the ideas attributable as predicates to the subjects in our judgments and of the various modes of being attributable to individual things as they occur in our experience. The Aristotelian categories have been accepted through the centuries, with some exceptions, as the finest set devised by the mind of man. In general, the scholastic philosophers of the Middle Ages and of modern times have embodied them in their system without alteration.

Some philosophers, as must be expected, are not altogether satisfied with the ten categories of Aristotle. They claim that some of them are not mutually exclusive and irreducible. Causal change, for instance, viewed from the standpoint of the agent, is 'action,' and viewed from the standpoint of the recipient, is 'passion' or 'reaction'; action and passion are thus only two phases of one and the same process. While this is true enough, it must not be overlooked that in most cases the agent and the recipient are two really distinct entities, and the causal change affects each one differently; there is reason, then, for making the distinction. In a real sense, too, 'quantity' enters into the concept of 'time,' 'place,' and 'posture.' Nevertheless, there is a difference in these concepts, and this difference seems large enough to warrant the placing of these ideas and modes of being in the list as separate categories. Even though only a *logical*, and not a real, *distinction* exists between some of these concepts, that should be sufficient, as long as there is a *foundation in the*

things themselves for making the distinction. A 'real' distinction hardly seems required, because it is the purpose and function of the categories to classify 'being,' not in an absolute sense, but according to the various modes in which it is attributable to some individual and according to the various ideas as predicated in our judgments. We must remember that Aristotle intended the categories to be primarily a system of *concepts* (universal ideas), and here a distinction in concepts suffices to list them as separate categories; only secondarily, in as much as concepts represent modes of being, did he intend them to be *ontological* categories. Hence, a logical distinction between the various categories, as long as there is a foundation for the distinction in reality itself, should suffice to give them a separate standing in the list.

In modern times, various attempts have been made to improve or supplant the categories of Aristotle. None were successful. The most ambitious of these substitutes are the categories of Kant. The objections against the categories of Aristotle are not of enough weight to offset the eminently practical division of all beings in the world as exemplified in this classification. Besides, tradition has sanctioned their use to such an extent that they have become almost an integral part of our language and mode of thought.

THE CATEGORIES OF KANT

Emmanuel Kant (1724—1804) sought to stem the tide of phenomenalism and skepticism which was running strong in his day, due to the philosophy of Hume. Kant's philosophy

ended in a phenomenalism even worse than Hume's. It is not within the province of ontology to give an exposition of Kant's principles; that belongs to epistemology.⁴ Suffice it to say, that he distinguishes between things-in-themselves and their phenomena. The things-in-themselves, or noumena, are the objects in the real world, independent of our thinking; but of these the mind can know absolutely nothing. The noumena excite our sensibility into action, and the result of this action is the production of phenomena or sense-intuitions through the subjective, innate sense-forms of 'space' and 'time.' These phenomena are the only things we can know, but they bear no resemblance to the things-in-themselves. The subjective forms of 'space' and 'time' are *a priori* present in the mind, anterior to all experience, and it is through them that experience becomes possible.

In order to obtain *intellectual knowledge*, our intuitions or phenomena must be brought under certain concepts or *categories* of the understanding; only in this manner can these intuitions become intelligible to us. The 'categories,' just like 'space' and 'time,' are subjective, innate, *a priori* forms of the understanding, and they must be united to the phenomena in order to make judgment and thought possible. These categories, therefore, are not derived from experience in any way; they are given with the mind itself and proceed from the mind. The things-in-themselves do not prompt the mind to form judgments about things by means of these categories. The application of the categories to the representations contained in the phenomena is altogether the action of a subjective law of the mind, and the resultant judgments tell us nothing about the things-in-

themselves and their modes of being; the latter are forever excluded from our knowledge.

Such is, in brief, Kant's doctrine of the categories. There are *twelve categories*, and for each there is a specific type of judgment. They are:

<i>Categories</i>	<i>Judgments</i>	<i>Example</i>
Quantity:	Quantity:	
(1) Unity	(1) Singular	This S is P
(2) Plurality	(2) Particular	Some S is P
(3) Totality	(3) Universal	All S is P
Quality:	Quality:	
(4) Affirmation	(4) Affirmative	S is P
(5) Negation	(5) Negative	S is not P
(6) Limitation	(6) Infinite	S is not-P
Relation:	Relation:	
(7) Substantiality	(7) Categorical	S is P
(8) Causality	(8) Hypothetical	If A is B, S is P
(9) Reciprocity	(9) Disjunctive	S is either P or Q
Modality:	Modality:	
(10) Possibility	(10) Problematic	S may be P
(11) Existence	(11) Assertoric	S is P
(12) Necessity	(12) Apodictic	S must be P

A glance at these Kantian categories will reveal the difference between them and the Aristotelian categories. The difference is fundamental and essential. The Kantian categories are *a priori mental forms*, absolutely independent of, and anterior to, all experience and the knowledge derived from experience. The Aristotelian categories are supposed to classify our knowledge of *reality*

as it exists outside the mind and as it is acquired through experience.

The Kantian categories have value *only for the mind* and its subjective operations. They merely bring the sense-intuitions or phenomena into a scheme of unity and give them necessity and universality. Since, however, the sense-intuitions or phenomena contain only knowledge which is purely subjective in character and does not reach to the noumena or things-in-themselves, the categories cannot tell us anything about the noumenal reality which lies outside and beyond the mind. Hence, the Kantian categories are not supreme classes of universal ideas and modes of being, but classes of *judgment-forms and modes of mental relations*. These categories give us no information about the objective content of the predicates or of the modes of being present in the things-in-themselves.

Kant calls these mental forms 'categories,' but the term is a misnomer. The notion of 'category' was clearly defined by Aristotle, and the term thereby acquired a definite technical meaning. This meaning had been accepted in the sense given by Aristotle for a period of over two thousand years and as such became fixed and traditional in the history of philosophy. For Kant, then, to use the term 'category' in the way he did, amounted to a distortion and falsification of philosophic language. This was unwarranted and unjustifiable, because the new meaning attached to the term 'category' was bound to produce a confusion of ideas. Aristotle and Kant simply do not mean the same thing, when they speak of 'categories.' As such, therefore, Kant's categories must be rejected as *arbitrary*. In no way can they

be considered a satisfactory substitute for the categories of Aristotle.

Following the subjectivistic trend of Kant's philosophy, modern theories of knowledge are more or less phenomenalist or idealistic. Quite naturally, these theories of knowledge affect the entire outlook on the external world. Many scientists and philosophers contend that we can know only the *appearances* of things, without being able to penetrate to the real nature of things. Notions like 'substance,' 'causal action and reaction,' 'time,' 'space and place,' and so forth, are undergoing radical changes. In consequences of such views the Aristotelian categories no longer carry the same meaning for many thinkers of our day as they did in times gone by. What the final outcome of these tendencies will be, no one can foretell. Up to the present, however, the categories of Aristotle can still be considered the best classification of the modes of being, and it is unlikely that they will be superseded.

PLACEMENT IN THE CATEGORIES

All things and modes of being must belong under some category, and it must be possible to place them there. This does not mean that all things and modes of beings, as we *conceive them in thought*, can be brought under a category directly. Due to the abstractive power of our mind, we often separate things in our thought which are united in reality and combine things in our thought which are not united in reality. Hence, it happens that we frequently conceive things to be different than they really are, and this

difference is manifested in our concepts and language. The 'family,' for instance, is considered as a unit in our concept, but in physical reality it consists of individual, really distinct beings. This general fact must be borne in mind, when we attempt to place something under a definite category. Philosophers, therefore, distinguish three different ways in which something may be placed in a category: *directly, indirectly, and reductively*.

In order that something fall under a category *directly*, a number of conditions are required. First of all, it must be a *real being*. It is the purpose of the categories to classify the modes of being which determine an 'individual being,' and it is only a 'real' being that can be an individual being. It is not necessary that a being actually exist, in order to be 'real,' because a possible or potential being is also 'real.' An actual or possible being belongs directly under a category; but a conceptual or logical being does not, because such a being is not a thing that can, as such, have reality except in the mind. Concepts like 'vacuum,' 'illness,' 'blindness,' 'paralysis,' etc., cannot be brought directly under a category; but concepts like 'man,' 'stone,' 'water,' 'iron,' 'body,' etc., are brought directly under a category.

Another condition demands that a thing must be, not an accidental, but a *natural unit* in its being; it must be a single essence, either simple (e.g., a pure spirit) or compound (e.g., a man). The reason for this condition is that what is not a natural unit in its being contains parts which may fall under more than one category. This condition excludes *collective* ideas, like 'family,' 'army,' 'flock,' 'library,' etc.; *complex* ideas, like 'paleface,' 'historian,' 'yellow orange,'

'black cat,' etc.; and *concrete adjectives* used as substantives, like 'sage,' 'American,' 'Indian,' etc. There is a double element in every such concept which hinders it from belonging to a single category. Thus, the term 'historian' involves two distinct concepts: a man (category: substance) who has a 'knowledge of history' (category: quality). But orange, man, dog, cat, water, wood, etc., are things with a natural unity in their physical being, as expressed by the concept itself, and they fall directly under the category of 'substance.' When, however, accidents are taken *abstractly*, like 'whiteness,' 'philosophy,' 'history,' 'warmth,' 'paleness,' etc., they belong directly to a category, because in such cases the concepts express only a single element or essence.

Furthermore, for direct placement in a category, a thing must be a complete being, and not a mere part of another being. We consider things here principally as they do, or can, exist as individuals. This condition excludes all *integral* parts of things, such as hands, feet, head, wings, heart, etc.; all *substantial* parts, like matter and form, body and soul; the *generic* element (e.g., 'sentiency,' in man) and *specific difference* (e.g., 'rationality,' in man), taken by themselves; and *modifications of accidents* (for instance, the 'intensity' of heat, the 'pitch' of sound, the 'voltage' of electricity, etc.). Complete beings, like man, horse, tree, gold, fish, bird, etc., are placed directly under a category.

Finally, only *finite beings* can be brought directly under a category. Only things, in which the term 'being' is used *univocally*, are predicamentally alike and belong together in the same category. It would be a case of logical violence

to place God and creatural beings together in the same class of 'substance,' because the distance which separates the infinite from the finite is immeasurable. The concept of 'being' or 'substance,' as applied to God and creature, is not univocal, but analogical. God is indeed a 'substance,' but a substance infinitely superior in every way to the substantiality of His creatures and as such infinitely beyond the category of creatural substance. The categories apply to beings of the *same order* only; consequently, they must be restricted to beings in the finite universe. God belongs to no category.

Such are the conditions for direct placement in the scheme of categories. Although not all realities can be brought directly under a category, they can be brought under them either *indirectly or reductively*. The differences which distinguish the *genera* and *species* of substances fall 'indirectly' under the category of 'substance.' Such would be concepts like 'rationality,' 'sentiency,' 'vegetancy,' 'materiality,' and 'spirituality.' *Parts* of things, beings with an *accidental or artificial unity*, and also *logical entities*, are brought 'reductively' under their corresponding categories. Thus, 'hands,' 'feet,' etc., 'family,' 'army,' etc., 'sage,' 'American,' etc., belong to the category of 'substance'; the 'intensity' of heat, the 'pitch' of sound, etc., to 'quality'; 'blindness,' 'illness,' 'paralysis,' 'toothache,' etc., to 'quality'; 'mathematical point,' 'curve,' 'triangularity' etc., to 'quantity.'

It might be asked: Why are not the nine categories, distinct from the category of 'substance,' placed under the *common genus of 'accident,'* so that there would be but two supreme categories, namely, *substance and accident*? For

one reason, the number would be too small, and the system of categories would no longer be serviceable in this abbreviated form. It would still be necessary to subdivide 'accident' into the other nine, in order to introduce a proper differentiation among the various concepts and modes of being. Besides, the concept of 'accident' cannot be said to apply univocally to the nine modes of being characterized by the various categories. An accident is defined as a being which needs a subject (substance) in which to inhere in order to exist. The common element in all accidents is that they 'inhere' in a substance. But this 'inhesion' is quite different in the various types of accidents. 'Thinking' and 'willing,' for instance, confer a distinct and new entity upon man; but 'place' and 'time' cannot be said to do that. Hence, the concept 'accident' applies only *analogically* to the various modes of being expressed by these nine categories. In that case 'accident' is not a true genus, and it is better to retain the separate standing of each category. However, even though one were to consider 'accident' a true genus, with a univocal application to everything that is not a substance, the practical purpose of the categories would still demand their separate enumeration.

After this general explanation it should be fairly obvious that the Aristotelian categories form a valuable framework for the classification of our knowledge of being and its modes.

SUMMARY OF CHAPTER XVI

The third part of ontology will treat of the ultimate and supreme modes of being. These are the *categories or predicaments*.

1. *Concept of the Category*. Aristotle changed the term 'category' from an expression in a court of law to a technical expression of philosophy and used it in the *logical* meaning of a supreme class of predicates in our judgments. Since, however, the predicates represent reality, he also gave the categories an ontological meaning. The ontological categories are the *ultimate and supreme modes of real being*.

2. *Principle of the Categories*. The number of categories must be neither too small nor too large; they must be natural divisions of the modes of being; and they must contain a complete classification. Since they are the supreme classes of the modes of being, and since 'being' and the 'modes of being' can be found only in individual beings, individual being must be the principle for the division and number of the categories.

3. *The Categories of Aristotle*. Aristotle distinguishes ten categories: substance, quantity, quality, relation, action, passion, place, time, posture, and habitus.

4. *The Categories of Kant*. Kant's so-called 'categories' are not categories in the accepted and traditional sense. They are *judgment-forms* and modes of *mental relations*. They are innate mental forms which tell us nothing about noumenal reality or things-in-themselves, since, according

to Kant, our knowledge is restricted to phenomena, and phenomena are only subjective constructs of the mind.

5. *Placement in the Categories*. All beings and modes of being can be placed in the categories either directly, indirectly, or reductively. For a *direct* placement the following conditions must be observed: the thing to be placed must be a 'real' being; it must be a 'natural unit' in its being; it must be a 'complete' being; it must be a 'finite' being. *Indirectly*, the differences which distinguish genera and species fall under a category. *Reductively*, parts of things, beings with an accidental or artificial unity, and logical entities are brought under categories.

Chapter 17

SUBSTANCE AND ACCIDENT

HAVING EXAMINED THE GENERAL NATURE OF THE CATEGORY and the reasons underlying its division into ten, we must now turn our attention to the single categories. The first and most important of these is substance. The other nine can, in a broad sense, be placed under the common heading of accident, for whatever is not a 'substance' is classified as an 'accident.' The division of all beings into 'substances' and 'accidents' is traditional in philosophy, but this tradition must be justified and cannot be taken for granted without proper proof. It is the duty of the ontologist to investigate the matter and furnish the reasons which prompt philosophers to divide all things in this manner.

CONCEPT OF SUBSTANCE AND ACCIDENT

A substance is a being whose nature it is to exist in itself and not in another as in a subject. An accident is a being whose nature it is to exist in another as in a subject. In order to obtain a better understanding of these definitions and of the nature of substance and accident, it will be necessary to analyze them somewhat more in detail.

From the *logical* standpoint of experience and knowledge, we first come to know the accidents of quantity, quality, and activity of things: namely, size, shape, weight, color, heat, odor, flavor, motion, growth, and similar realities. Then, observing the relative permanence and identity of the thing, notwithstanding the manifold modifications and changes which occur in it, we come to know the underlying subject or substance. The substance, therefore, is conceived as being the underlying subject or support (Lat., *substantia*, *substans*, from *substare*, to stand under, bear, support) of the accidents, while not being supported in its being and existence by another. The accident (Lat., *accidens*, from *ad* and *cadere*, to fall to or upon, to rest on) is conceived as being something which requires a subject to inhere in, so that it has the necessary support for its being and existence, because it cannot exist except in another being. From the *ontological* standpoint of being and existence, the substance is first and the accident follows, because the accident is only a modification of the substance and therefore presupposes the presence of the substance before it can itself have being and existence in the substance.

A substance, then, is a being which possesses sufficient entity of its own to exist independently, so that it does not exist in another as *in a subject* which must support it in existence. The meaning is: Among beings and realities existing in the universe, substances are mutually independent beings, each capable of existing in itself as a self-contained thing, without the need of another being in which it must inhere in order to have existence. Shape and

size, for instance, exist in man as in a subject; but man himself is an ultimate thing which does not again exist in something else.

We may look at 'substance' in two ways: as a thing in itself, and as a support of accidents. Obviously, the *primary* concept of substance is that it is a *thing in itself*; it is a secondary concept to consider it as a subject of modifying accidents. It is but natural that a thing must be something in itself before it can be something *for others*. Even if it had no modifying accidents at all, it would have its own entity and as such would be a true substance, because it would still be a thing existing in itself. In this manner God, who has no accidents in His being, is a substance *par excellence*, because He already possesses in the infinite perfection of His substance whatever entity accidents could possibly confer upon Him. Accidents necessarily presuppose the concept of 'substance,' but substances do not postulate the concept of 'accident.' Consequently, we do not define 'substance' as the subject of accidents, but as a being whose nature it is to exist in itself and not in another as in a subject.

THE ACCIDENT IS DEFINED AS A BEING WHOSE NATURE IT IS TO exist in another as in a subject. The categorical accident always presupposes a subject of which it is a modification, and this subject is ultimately a substance. 'Ultimately'; because it would be erroneous to think that every accident must inhere immediately in the substance. One accident may inhere *in another accident* as in its *direct* subject;

shape, for example, is an accident directly modifying quantity, and quantity is an accident directly modifying a material substance, so that shape modifies the substance only indirectly. Ultimately, of course, shape modifies the substance and must inhere in the substance as its fundamental subject and support.

Every accident demands inherence in a substance. However, one must avoid a too crude conception of this *inhesion*. Accidents are not a sort of outside coating or covering for the substance, nor are they to be considered as foreign and extraneous realities attached to the substance or permeating its being. Accidents are rather *determinations and differentiations* of the determinable and indifferent substance. The substance has certain potentialities which demand development and actualization, and the accidents are the *actualizations* of these potentialities. To give some examples. The human soul possesses an intellect, but the intellect needs the determination of active 'thinking' in order to become actualized; this active 'thinking' is, therefore, a perfecting accident of the intellect. Man also has the power or potentiality of sense-perception, but this potentiality must be actualized before it can be of any use to man; this actualization takes place in the acts of sight, touch, hearing, etc., and these acts of sensation are accidents which bring the power of perception to its natural completion. Thus all accidents are a fuller realization of the substances which they modify.

The definition of accident was formulated in such a manner that it was said to be 'a being whose *nature* it is to

inhere, etc.’ It was advisedly not stated to be a ‘being *which inheres* in another.’ Strictly speaking, it is not essential to an accident to *actually* inhere in another as in a subject. Science and philosophy, it is true, know of no case where accidents exist outside their substance. Nevertheless, the essence of an accident would still be the same, and an accident would always remain an accident, even if it were to exist outside its subject, provided its *nature* requires that it normally exist in a substance. To exist outside its subject would indeed be an abnormal condition for an accident. This, however, would not change its essence, because it would retain the *natural necessity* and *aptitude* to inhere in a subject. It could never lose this ordination toward its substance. The essence of an accident naturally demands inhesion and this demand would accompany it even outside its subject; it would, therefore, never become ‘substantialized’ by the mere fact of being detached from its substance.

This distinction between actual and aptitudinal inherence of an accident in its substance is of great importance in the doctrine of the Holy Eucharist, where the accidents of shape, color, extension, etc., are deprived of the natural support of the bread-substance and wine-substance after consecration and are preserved by divine power outside any substance. Because of the natural aptitude and exigency of inhesion, they are still ‘accidents’ and do not become substances.¹

Hence, this ‘aptitudinal inherence’ is an essential characteristic of an accident, but the ‘actual inherence’ is

only a normal condition for it; God's omnipotence could detach an accident from its substance without destroying its essence.

KINDS OF SUBSTANCE

Substance can be viewed from different standpoints. A number of divisions of substance can be made, each representing a different *kind* of substance. We will now examine the main classes.

Primary and Secondary Substance. For a proper understanding of this division of substances, we must go back to the days of Plato and Aristotle. *Plato* (427 or to about 348 B.C.) made a serious attempt to account for the universality and necessity of our scientific knowledge. Since our scientific knowledge is supposed to be universal and necessary in its scope, it must be a true representation of *reality*; as such, then, the reality, from which our knowledge is derived and which our knowledge represents, should itself be 'universal' and 'necessary.' Plato could find no such universal and necessary realities anywhere in the physical world as we observe it: all things are individual, not universal; and they are not necessary, but in a continuous process of generation and dissolution. The things of this world, therefore, Plato contended, cannot be the reason for the universality and necessity of our knowledge. Since, however, the 'concepts' or 'ideas' of our mind represent the essence of things, he concluded that the 'concept' or *Idea* is the only reality which is permanent and unchangeable. The *Idea* must, then, be the very essence of the reality' of

‘being’ and of the reality of scientific ‘knowledge.’ Such Ideas would have to be universal and necessary, existing independently for themselves, apart from the concrete things in the world and from the concepts of our mind; they would be the patterns or exemplars according to which these concrete things and our concepts are fashioned. The physical objects would be faint copies of these Ideas, and our concepts would be intellectual copies of these same Ideas. These Ideas exist in a world of their own as essences and substances, unchangeable and eternal. Hence, these *Ideas* are the *primary substances* and the *individual substances are secondary substances*.

Aristotle attacked Plato’s ‘world of Ideas’ as fanciful, poetic, and superfluous. He contended, and rightly, that we derive our universal ideas of things from our observation of the *things themselves*, not from a contemplation of eternally existing Ideas. When we form the universal idea ‘man’ as applicable to the whole class of men and to every individual man, we do so through a process of mental abstraction; we leave aside the individuating characteristics which differentiate one individual man from another and select (‘abstract’) those elements which all individual men have in common with each other. In this manner we arrive at the universal idea of ‘man’ or of a ‘rational animal’; it applies to all men as a class (e.g., ‘*Man* is mortal’) and to each individual man (e.g., ‘*This man* is mortal’). Aristotle is correct in his view that we derive our universal ideas through abstraction from individuals.² The concept ‘man,’ therefore, applies primarily to the individual human being and only secondarily to the species or class. Therefore, the

individual ('this man') is the *primary substance*, and the substance expressed by the *universal idea* ('man' in general, as a species or class) is a *secondary substance*.³

Every individual substance is a primary substance: every single inanimate body (every bit of gold, paper, wood, air, etc.), every single plant (every rose, elm, bush, grapevine, etc.), every single animal (every dog, elephant, etc.) and every single man (Washington, Napoleon, Lincoln, etc.). *All universal ideas*, representing substance as a class, are secondary substances: man, animal, organism, body, substance, plant, fish, bird, etc., taken as a species or genus.

Complete and Incomplete Substances. All primary substances are either complete or incomplete. A substance is *complete* when it exists in such a manner that its nature demands no further union with a substantial co-principle. When a substance is complete, it possesses everything that its constitution and essence requires for its existence and for the proper functioning of its natural activities. Thus, every human being, consisting of body and soul, is a complete substance, capable of existing and of performing its natural functions of vegetancy, sentiency, and rational life; in like manner, every brute, plant, and inorganic body are complete substances.

A substance is *incomplete* when its nature demands that it be conjoined with some other substantial co-principle, so as to constitute a complete substance. Each substantial part or principle, taken alone, would be insufficient to exist, or, at least, would be insufficient for all the functions of an individual of that particular species. It must be borne in

mind that we are speaking of *substantial parts*, not of accidents. Thus, man soul alone, without his body, could not perform the functions of vegetancy and sentiency (for example, digestion and sight) which functions are also natural operations for man; man needs a material body for them. Neither could man's body alone, without the soul, perform the functions of thinking and willing; man needs an intellectual soul for them. Hence, body and soul, each considered alone and in itself, are incomplete substances; they are substantial parts or co-principles which must be united into a single whole, in order to make a compound nature capable of all the functions proper to it.

A substance may be *incomplete* in two ways; in the line of 'substantiality' or in the line of 'specific perfection.' It is incomplete in the line of *substantiality*, when it cannot perform any functions of the complete substance *alone*; it must always be united with its substantial co-principle. In this way, the brute soul and plant soul cannot exist outside the matter which they inform and cannot, therefore, be active in any manner unless united with matter; the functions of these types of being are such that they are dependent on matter at all times for their existence. Matter, the other co-principle, is incapable of performing any activity of its own, because it is altogether indeterminate and cannot exist except in conjunction with a substantial form or soul. Matter and form are the two substantial co-principles which unite to constitute a bodily substance; and in every bodily substance below the level of man these substantial co-principles are incomplete in the line of substantiality.

A substance is incomplete in the line of *specific perfection*, if it can, when alone, perform *some* but *not all* activities proper to the complete substance. Thus, the human soul, being spiritual (as will be shown in rational psychology), can survive the dissolution of the body and in this disembodied condition perform some functions proper to man, for instance, thinking and willing. This is possible because such functions are spiritual and as such intrinsically independent of matter. Other operations, however, like nutrition and sense-perception, demand the participation of bodily organs and cannot be performed by the soul alone. Man, as man, though, must be able to perform all three types of activities vegetancy, sentiency, and rationality. Hence, man's soul is complete in the line of 'substantiality,' because it is independent of the body in its existence; but it is incomplete in the line of 'specific perfection,' because it cannot perform *all* human operations independent of the body.

SIMPLE AND COMPOSITE SUBSTANCES. ALL COMPLETE SUBSTANCES are either 'simple' or 'composite' in their nature. They are *simple*, when they do not consist of entitatively distinct *substantial parts*. Such simple substances are called *pure spirits*, for instance, angels or God. Complete substances of this kind are 'absolutely simple.' However, one can speak of certain substances as 'naturally simple' in a wider sense of the term 'simple.' By 'naturally simple' substances one would then understand substances which consist of parts which are material and entitatively distinct, but naturally

indivisible and inseparable. The ultimate physical components of the universe (perhaps protons and electrons) would be 'naturally simple' in this sense; and also, according to the view of some aristotelian-scholastic philosophers, the forms or souls of plants and animals.

A *composite substance* is a complete substance consisting of incomplete *substantial parts*, entitatively distinct among themselves, in such a manner that their union results in a single, *unified nature*. In a composite substance neither of the incomplete part-substances inheres in the other as in a subject of inherence; they complement each other, making a single principle of natural functions through their union. Man, for instance, is a composite substance consisting of body and soul. The soul does not inhere in the body, as an accident inheres in its subject; nor does the body inhere in the soul. Neither do soul and body merely co-exist side by side, as if each were independent of the other in its functioning. Soul and body form a natural unit, a *single nature*, so that man is not two things, but *one substance*; in consequence of this substantial composition man, as a unit, is capable of spiritual and material vital activities. Our consciousness testifies to the fact that we are not two things or substances, but one. Man, therefore, is a composite substance. So, too, is every animal and plant; they possess not only chemical and physical properties and activities, but also properties and activities which are immanent and therefore vital. Whether chemical elements (e.g., radium, helium, hydrogen, oxygen, etc.) and chemical compounds (e.g., water, carbohydrates, carbon monoxide, etc.) are

composite substances with a single substantial form, is a mooted question. The theory of matter and form (hylomorphism) belongs properly to cosmology and will be treated there.

Every composite substance is, then, a *substantial unit* (*unum per se*), not an accidental unit (*unum per accidens*). A thing is said to be an 'accidental unit,' when it consists of two or more complete substances collaborating in a unified combination and action, while each component retains its substantial entity in the arrangement of the whole. A few examples will clarify this notion. A 'hive' of bees is a unit; since, however, each bee remains a complete substance in itself, a colony of bees is only an accidental unit. Soldiers and officers form an 'army' with a unified action; but an 'army' is only an accidental unit, because the soldiers and officers are obviously not merged into a single substance and nature. The difference between such an 'accidental unit' and a man or an animal or a plant as a 'substantial unit' is evident: the compound of body and soul in man and animal and plant is such that they are a single principle of action, a single nature, a single substance; their functions proceed from the *whole* as a *unit*, and that 'whole' is not accidental or artificial, but substantial and natural.

KINDS OF ACCIDENTS

Accidents, like substances, can be viewed from different standpoints and classified accordingly. The following are the main kinds of accidents.

Relative and Absolute Accidents. By 'relation' we mean the bearing which one thing has to another. There are always two terms to a relation: the 'relative' or thing relating, and the 'correlative' or thing related to. A *relative accident*, therefore, is an accident that has its being in a subject only because of the bearing which one thing has to another. More will be said about relative accidents in a subsequent chapter.

An *absolute accident*, on the other hand, is one that confers a *real perfection* upon its subject. *Extension* or quantitative dimension is such an accident. To be 'large' or 'small' is a matter of comparison with another object, but no object can be styled 'large' or 'small' in any sense unless it inherently possesses quantitative dimensions in *itself*, so that it can be compared with the quantitative dimensions of other objects. It is because of such dimensions (extension) that a body occupies space, is measurable, and can be divided; but all this presupposes parts beside parts in the object. Such parts are a real perfection for a thing. Again, *qualities* are absolute accidents. The potential energy of physical bodies; the power of nutrition, growth, and reproduction in plants; the faculties of sensation in the various sense-organs of an animal; intellect and will in man: all these things are a perfection for these respective substances. Furthermore, *activities* are absolute accidents. The physical actions of bodies as effected through kinetic energy, the vital functions of plant, animal, and man — these are accidents which confer perfection upon the substance performing these activities. When we walk,

digest, see, hear, feel, think, and will, our nature actualizes its powers and acquires perfection thereby.

Strictly Absolute and Modal Accidents. There are two kinds of absolute accidents: strictly absolute and modal. A *strictly absolute accident* is one which affects a substance in such a manner that it actually confers upon it some *positive* and *new entity*. Such an accident, though it inheres in a substance and needs the substance as a support for its existence, possesses an entity of its own, distinct from the entity of the substance. Such would be the various types of accidents mentioned above in the preceding paragraph.

A *modal accident* or accidental mode is the definite disposition or determination of an indifferent and determinable entity, without conferring any positive and new entity upon the substance. It is something real, but it does not possess any entity of its own, distinct from the entity of the substance itself. Shape, being in motion or rest, being in time (*quandocation*) and place (*ubication*), and posture belong to this class.

Such modes are something *real*; they are not 'nothing,' nor are they logical entities existing only in the mind. It makes a difference in the real order, whether a thing have this or that shape, whether it be at rest or in motion, whether the motion be straight or curved, whether it be in a high or a low place, whether its movements occur today or tomorrow, whether it have this or that posture. These modes *change* in the real order of things, and that shows that they are neither 'nothing' nor a mere logical entity.

Intrinsic and Extrinsic Accidents. *Intrinsic accidents* are such as affect the *being* of the subject in some way or other;

as such they are internally united to the subject and modify it entitatively. Absolute accidents are of this kind. The quantity of a 'body' as manifested in its three dimensions of length, breadth, and depth, is a positive accidental entity affecting the being of the material body. All qualities, whether material or spiritual, have the same character. All actions of bodies, immanent as well as transient, also belong to this class of accidents.

The case of *extrinsic accidents* is very different: they are accidents which *do not affect the being* of their subject; but they affect it indirectly by modifying the subject's immediate surroundings. *Habitus* is such an accident. It makes a difference to a person to be clothed or unclothed, to be barefooted or booted, etc. It is obvious, however, that such modifications are entirely *exterior* to the person and do not affect his being as such in any direct and intrinsic manner.

KNOWLEDGE AND SUBSTANCES

David Hume (1711—1776) denied the existence of all substance, material and spiritual. "I would fain ask those philosophers, who found so much of their reasonings on the distinction of substance and accident, and imagine we have clear ideas of each, whether the idea of *substance* be derived from the impressions of sensations or reflection? If it be conveyed to us by our senses, I ask, which of them; and after what manner? If it be perceived by the eyes, it must be a color; if by the ears, a sound; if by the palate, a taste; and so of the other senses. But I believe none will

assert, that substance is either a color, sound, or taste. The idea of substance must therefore be derived from an impression of reflection, if it really exist. But the impressions of reflection resolve themselves into our passions and emotions; none of which can possibly represent a substance. We have, therefore, no idea of substance, distinct from that of a *collection of particular qualities*, nor have we any other meaning when we talk or reason concerning it."⁴

Hume's argument for the sole validity of our knowledge of phenomena underlies many modern theories of knowledge. The only means of contact that man's mind has with the outside world is the system of his senses. Consequently, the mind of man can know nothing but phenomena. For the mind to attempt to penetrate beyond the phenomenal world is a futile and illegitimate procedure. We must deny the existence of anything beyond phenomena, or, at least, we must treat that which lies beyond as the 'unknown and unknowable.' Phenomenalism may admit the existence of motion, weight, color, extension, action, thought, volition, and similar realities of a passing character; but *there is no thing underlying them* which moves, is heavy, is colored, is extended, acts, thinks, wills, etc. If we still think of some 'hidden substance' as the support of these phenomena, this is but a creation and fiction of the mind. The concept of 'substance' has no objective value.

What are we to think of this argument and its implication? Is it conclusive? Is our mind irrevocably restricted in its knowledge to the phenomenal? Is there no

way of penetrating the veil of appearances? The array of opposing opinions is certainly formidable and must not be treated lightly.

We admit that our senses, as such, do not and cannot perceive 'substance,' but only the *qualities* of things or phenomena. In this sense it is true to say that we do not *experience* that which we call 'substance.' If our knowledge is absolutely circumscribed by 'sense experience,' we must admit that we can have no knowledge of 'substance.' However, is this truly so? Empiricists, sensists, materialists, and phenomenologists in general all assert this to be the case. We deny this most emphatically. Unfortunately, the entire question of the validity of human knowledge plays an essential part in the solution of this problem. The problem of human knowledge, however, is the problem of epistemology, not of ontology. The ontologist presupposes the validity of human knowledge as already definitely established. Hence, a few remarks must suffice in this connection.

Man's knowledge is not restricted to experience; it is based on *experience* and *intellection*. Man has not merely a number of senses, but also *understanding* and *reason*. Reason is as much a part of man's mental equipment for acquiring knowledge as the senses are. Knowledge for man begins in sense experience, but is completed, extended, and perfected by reason. There can be no science or philosophy without the use of reason; the senses alone are inadequate for this. Animals have sense experience like man; but, unlike man, they manifest no signs of science or philosophy. Reason must be accepted *as a legitimate source of*

knowledge. To deny this means to deny the legitimacy of all sciences and philosophy. But in that case the phenomenals refute themselves, because their theories are not 'experience' but 'philosophy.' They use their *reason* to arrive at the conclusions of their theory of knowledge: they do not taste or smell or see or hear or feel them. Now then, reason either is a legitimate means of knowledge, or it is not: if it is, phenomenals are wrong in restricting our knowledge to sense experience and phenomena; if it is not, their theories must be rejected as futile, because they are based on the conclusions of their reason.

As a matter of fact, no one can deny the legitimacy of reason and reasoning without falling into universal skepticism. Reason must *interpret* the data of sense; only in this manner can we have science and philosophy. Though our senses can directly perceive nothing but the qualities or phenomena in nature, our *reason can draw necessary conclusions* from the data of these qualities or phenomena. *Science* does this continually. It deduces the laws of nature from phenomena and expresses them in exact mathematical and logical formulas. These laws and formulas, however, are not objects of sense in any manner; they are conclusions of reason, based on the data of sense. As such they go 'beyond and behind' the phenomena which are perceived in sense experience. If this procedure is illegitimate, then science itself is illegitimate. And in that case all thinking and reasoning is illegitimate. That, however, would be skepticism and the bankruptcy of all knowledge. The legitimacy of reason and reasoning, therefore, must be upheld and maintained as a means of knowledge.

If, then, reason forces us to the conclusion that the phenomena alone are an insufficient explanation of the facts as revealed in sense experience, we must follow the dictates of reason to its logical conclusion. And if this means that reason demands the existence of an underlying substrate or 'substance' for the phenomena, in order that we can account for the existence of these phenomena themselves, we must perforce accept the existence of 'substance.' To refuse to accept such a 'substance' would then do violence to reason, and that would be the suicide of reason and the destruction of our knowledge in all its departments. *Sense and reason*, experience and intellection, must go hand in hand and guide us in our investigation of the problem. Experience without intellection would give us merely a chaotic mass of facts, but not the systematic interpretation of science and philosophy; intellection without experience would give us a world of abstract and speculative ideas, but would tell us nothing of the universe around us. Hence, the problem of the existence of 'substances' in the universe can only be solved by our *reason*, applying itself to the data furnished by *sense experience* and drawing the necessary conclusions.

THE EXISTENCE OF SUBSTANCE

In proving the existence of substance it should be borne in mind that it is not essential for a substance to possess accidents inhering in it; so long as it exists in itself and not

in another, it must be designated a 'substance' in the traditional sense.

Our first argument is based on *reality and the concept of substance* as just given. All that we presuppose for this argument is the concept of 'substance' and 'accident' and the existence of actual beings. The existence of *actual beings* cannot be denied. We ourselves, at least, exist. Were anyone to deny his own existence, he would prove his own existence by his very denial: for no one can possibly make a denial, if he does not exist. And as long as one admits one's own existence, one cannot logically deny the existence of other beings. Actual beings, therefore, must be admitted, otherwise there would be no sense in arguing about the reality of 'substances' and 'accidents.' The opponents all admit the existence of phenomena; there is only a question about the existence of substances. The argument is really quite simple:

Actual beings exist. Whatever exists, exists either *in itself* and not in a subject, and then it is a substance, or not in itself but *in another*, and then it is an accident. This exhausts every possible way of existing. To admit the first alternative settles the question, because one thereby admits that substance exists. Hence, if phenomena exist without underlying subjects, they are simply 'substances' in the sense defined. The opponents, in denying the existence of substances, have no other choice but to say that whatever exists must exist in another. But this, too, ultimately proves the existence of substance. Since it exists in an-other, they must necessarily postulate this 'other in which it exists as in a subject; this 'other,' however,

supporting it in its existence as a subject of inherence for it, is a 'substance' thereby. Hence, substance exists.

Their only means of escape from this conclusion would be to assert that every accident (quality, phenomenon) exists in *another accident* (quality, phenomenon), and this second in a third, and so on; we would thus have a *series* of supporting accidents. This series, however, is either finite or infinite. If *finite*, there must be a last one at the end of the series; this one, being the last in the series, has no other to exist in; it must exist in itself and not in another; and it is, in consequence, a substance supporting the other accidents, because it fulfills the conditions contained in the definition of a 'substance.' If *infinite*, then we have an infinite number of accidents inhering in each other serially. However, the assumption of an infinite number of accidents piled upon each other, simply to explain the red color of a rose or the round shape of a ball or the incandescence of a filament, is really too absurd. Besides, an actually infinite number, as will be shown later, is self-contradictory. But if the opponents still insist on an infinite number of accidents, one inhering in the other, then the following point can be urged. Does this infinite series exist in itself or in another? If *in itself*, it is a being which exists in itself and not in another as in a subject; as such it would be a substance, and thus a 'substance' would again exist. If *in another*, this infinite series of accidents would presuppose this 'other' as the subject of its inherence; this 'other' must be a substance and cannot again be an 'accident,' since there would then be an 'accident' which is *outside* the infinite number (series), giving a number which would be *one plus*

the infinite number. This is absurd, because it is impossible to have a number greater than infinite: in that case the supposedly 'infinite' number never was infinite, but finite. Since an infinite series of accidents inhering in each other is thus seen to be impossible, the number can only be *finite*; a finite number of accidents, however, demands an ultimate subject for the series, and this ultimate subject is a 'substance.'

Since, in short, things do exist and not all can be accidents, some must be substances. Hence, substances exist.

Our second argument is based on the *conscious Ego and the concept of substance*. Our consciousness, as was indicated above, is a clear witness to the fact that our Ego is the permanent subject of our willing, thinking, walking, resting, working, eating, smoking, growing, pleasure, pain, anger, love, etc. This means that the Ego, our 'self,' is the subject of all these changes, modifications, and qualities, bodily and mental. We perceive not merely the presence of these phenomena or passing states as existing realities; we recognize them undeniably *as our own*, i.e., that our *Ego possesses* them. This is evident from the way we speak of them. We say: '*I think,*' '*I walk,*' '*I love,*' etc. If the Ego were not the underlying subject of inhesion for these various states and activities, we could have a knowledge of their 'existence' only; our conscious experience should never prompt us to refer them to a non-existent Ego as the one to whom they belong and in whom they occur.

And this Ego as subject is also recognized as a *substantial* subject of these phenomenal realities. We know

through self-consciousness that the Ego is not an act or a state or a modification of some *other* subject underlying itself; it is an *ultimate* reality, existing in itself. The Ego never refers its states and activities to an ulterior being beyond itself as to their subject.

All the functions of mental life, like thinking and willing and emotional states, are referred to the Ego; so, too, are the bodily activities, like walking, eating, and growing. The Ego is the ultimate reality to which they are referred as their *possessor*, and nothing is experienced which could be designated as the ulterior possessor of the Ego. Hence, our Ego must be adjudged 'a being existing in itself and not in another as in a subject.' Since we may not doubt the testimony of our consciousness, the Ego must be a *substance*, because the definition of 'substance' applies to it.

Now, just as we must conclude that the Ego is a real substance, we must conclude that there are subjects for the changes and modifications (phenomena) in the world about us. There can be no 'extension' in the world outside without there being 'something extended'; there can be no 'squareness' or 'roundness' without there being 'something square' or 'something round'; there can be no 'motion' or 'action' without there being 'something moving' or 'something acting'; there can be no 'heaviness' or 'solidity' without there being 'something heavy' or 'something solid.' These qualities are phenomena; but the '*something qualified*' must be a *substance*. This is a legitimate conclusion, based on our own internal experience and carried over to the field of our external experience.

SINCE THE DAYS OF LOCKE, IT HAS BECOME CUSTOMARY TO THINK of 'substance' as some sort of hidden, inert, inactive core upon which the qualities rest. This is a misconception. It is *no such inert, inactive being*. Water may flow, boil, freeze, turn to steam. Just what is the 'substance' here? It is the very 'water' itself. Gold is a metal, yellow, malleable, ductile, heavy. What is its substance? The 'gold' itself, which is actualized as metal, yellow, malleable, ductile, heavy. The substance is the *intrinsic* nature of things, considered as the source of the various states and activities which we perceive. *Something* certainly *remains constant* and *permanent* in such changes and activities; it is the 'nature' of the thing, and this 'nature' is the 'substance.'

Again, opponents labor under a misconception when they speak of substances as something 'unknown and unknowable.' Of course, if they mean that we do not have direct sense-apprehension of substance, they are correct. But neither do we have a direct intuition of atoms, electrons, and similar things; yet we know a great deal about them through their *effects*. The same is true of 'substances.' Every physical body is a substance, and science tells us many things about bodies. Everything we know concerning the quantity, quality, and activity of a thing is a manifestation of its substance, because they are the *actualizations* of the substance. What things *do*, tells us what they *are*. After all, the knowledge of science is, to a very great extent, just this kind of knowledge. For example, our knowledge of the energies of nature consists entirely in

what they can or cannot perform; and such, too, is our knowledge of the molecular, atomic, and sub-atomic world. Molecules, atoms, protons, electrons, and kindred realities, are substances. Needless to say, all bodies like minerals, metals, solids, gases, fluids, chemical compounds, plants, animals, men, and stars, are substances. No one can say that such things are unknown and unknowable. In calling them 'substances,' we merely wish to indicate the *manner and mode of their existence*, namely, that they are beings which exist in themselves and not in another as in a subject. The distinction, therefore, between such things (substances) and their modifications (accidents) simply adds one more important item of information to our store of knowledge concerning them. If the opponents understand anything else under the terms of 'substance' and 'accident' than this traditional definition and explanation, they place a false interpretation upon them and are guilty of fighting straw men of their own making.

EXISTENCE OF ABSOLUTE ACCIDENTS

Descartes denied the real distinction between accident and substance, contending that there are no *absolute accidents*, i.e., no accidents which communicate a positive and new perfection or entity to the substance which the latter would not already possess as a substance. His view, and that of his followers, was that accidents are only 'determinations' of substance which consist in a difference concerning the *position* and the external connection of the *parts* in a substance, or in a difference concerning the *bearing* of one

substance toward another. This would mean that there are only *relative accidents*.

This view is *erroneous*. Certainly, many accidents are merely relative; for instance, those of 'similarity' and 'equality' between two individual substances. The mere fact that two persons or trees are five feet and ten inches tall, does not give to either of them any positive and new perfection or entity beyond what they already possess; their 'equality' in height consists entirely in this 'point of comparison or relation. The same applies to the 'similarity' between a horse and a cat, because they resemble each other in this that both are 'white' in color. But not all accidents are of this kind. *There are absolute accidents*. In proving this statement, we will restrict ourselves to facts revealed by our own internal experience, because no philosopher can doubt this evidence without destroying the ultimate possibility of all valid knowledge.

Our *internal experience* testifies to us that there are various modifications within us, like thinking, willing, seeing, hearing, feeling, walking, working, and various kinds of productive activity. To deny these activities is to make an illusion of our internal experience as a source of knowledge. These activities are a *reality*, distinct from our fundamental essence or substance. They are present for a time and then disappear; we exert ourselves to increase or decrease their intensity; we are actively engaged in bringing them forth or stopping them. These activities confer a new perfection and entity upon us which was not there before. Would anyone assert seriously that a blind and deaf person does not lack something which one who

sees and hears possesses through the activity of sight and hearing? Or, that a healthy person does not possess a perfection and entity which a critically ill person has lost? If so, then there is no real distinction between blindness and sight, deafness and hearing, health and illness; but that is obviously false. However, while these activities come and go, we still retain our *essential identity* as an abiding and permanent reality throughout the origin and passing of these transient modifications. But this proves that we are a *substance*, while these acts are a positive perfection and entity consisting in something more than the mere relation of one thing to another; more, for instance, than the relation of 'similarity' between the light of an electric lamp and the light of a star.

Knowledge, too, is more than an accidental relation. If it were nothing real superadded as an entity to the mind, then the mind with knowledge would not be really different from the mind without knowledge. Ignorance and knowledge would really amount to the same thing for a mind. But the mind undergoes a *change*, when it passes from a state of ignorance to a state of knowledge, as our consciousness clearly testifies. Change, however, implies that something is actually acquired (or lost) in the process. Reversely, when we forget or are the victims of amnesia, we realize that we have lost something definite in the line of a perfection for our mind; not the mind itself, of course, because that we still possess, but something that the mind had and now is deprived of. If knowledge were not a real perfection, we would acquire nothing when we learn, and we would *lose* nothing when we forget; there would then be

no real distinction between the erudition of a great thinker and the vacuity of an idiot. Hence, knowledge is *something* that can be acquired and lost, an accident that is a reality distinct from the mind. The *effort* we put forth in order to learn proves the same thing. It takes no effort on our part to be similar to another in the color of our complexion or equal to another in our size. But to acquire a knowledge similar or equal to that possessed by another, demands distinct effort and labor. And this proves that knowledge is more than a mere relation or relative accident; it is an absolute accident.

This brief examination of the various kinds of substances, accidents, and modes should give us a better understanding of the different ways in which 'being in general' is realized in the things which constitute the totality of the universe.

SUMMARY OF CHAPTER XVII

The division of all beings into 'substance' and 'accident' is traditional in philosophy.

1. *Concept of Substance and Accident.* A *substance* is a being whose nature it is to exist in itself and not in another as in a subject. An *accident* is a being whose nature it is to exist in another as in a subject. This 'aptitudinal inherence' is the essential characteristic of an accident, while 'actual inherence' is its normal condition.

2. *Kinds of Substances.* Primary and secondary substances. The former are the individual substances; the latter are the class-substances (e.g., species and genus) expressed by universals. *Complete* and *incomplete* substance. The former is one which demands no further union with a substantial co-principle; the latter demands a union with a substantial co-principle in order to constitute a complete substance. *Simple* or *composite*. The former does not consist of entitatively distinct substantial parts; the latter consists of incomplete substantial parts, entitatively distinct.

3. *Kinds of Accidents.* *Relative* and *absolute* accidents. The former have their being in a subject only because of the bearing which one has to another; the latter confer a real perfection upon their subjects. Absolute accidents are either *strictly absolute* or *modal*. The former confer a positive and new entity upon the substance; a mode is the definite disposition or determination of an indifferent and determinable accidental entity in such a manner that it

does not confer a positive and new entity upon the substance. *Intrinsic* and *extrinsic*. The former affects the being of the subject in some way; the latter merely affects the subject's surroundings, but not its being.

4. *Knowledge and Substance*. Hume and the phenomenologists contend that we can know nothing of 'substances,' because our senses can reach only the qualities of things. Reason, however, is also a legitimate source of knowledge. Science and philosophy are based on *experience and intellection*. Hence, if reason demands the acceptance of 'substance,' we must conclude that 'substance' exists.

5. *The Existence of Substance*. Actual beings exist *either in themselves or in another*. If in themselves, then 'substance' exists, because that is what is meant by the term. If in another, then this 'other' is the subject supporting the former in their being and existence; in that case, 'substance' exists, because this 'other' exists in itself and not in another as in a subject. It is impossible for all beings to exist in another serially, because that involves an infinite number, and an infinite number, actually existing, is absurd.

Our *conscious* Ego is the *possessor* of all internal states of our being. The Ego is the ultimate subject to which all such states are referred, but the Ego itself is not referred to any ulterior subject. Hence, it exists in itself and not in another as in a subject; and that is the definition of a 'substance.'

6. *Existence of Absolute Accidents*. Not all accidents are relative; some are absolute. Our internal experience

testifies that we actually acquire a positive and new perfection or entity through thinking, sense-perception, and other activities.

Chapter 18

ESSENCE, NATURE, HYPOSTASIS, PERSON

A NUMBER OF CONCEPTS ARE CLOSELY ALLIED TO THAT OF 'substance.' Their meanings are so very much alike that they are frequently used synonymously. These concepts are *substance, essence, nature, hypostasis, and person*. It would be incorrect, however, to consider them as strictly synonymous; there is a distinction between them which it is important to note. These terms have occurred many times in the preceding chapters, with the exception of 'hypostasis.' We must now give them serious attention, in order to see in how far they agree in meaning and in how far they disagree. In the course of the history of philosophy these terms have given rise to some problems which have occasioned considerable controversy; these we must attempt to solve.

SUBSTANCE AND ESSENCE

We have already discussed the meaning of *essence* (see Chapter 10). In a general sense, it is defined as that through which a being is just what it is. Taken in this general sense, every being of whatever kind has an

‘essence,’ because every being without exception ‘is what it is,’ and there must, therefore, be that in it which makes it to be ‘what it is.’ And since all being must be either ‘substance’ or ‘accident,’ it follows that every substance has an ‘essence’ which makes it to be a ‘substance,’ and every accident must have an ‘essence’ which makes it to be an ‘accident.’

In a concrete, individual being it is the *substance* which makes it to be ‘*what* it is.’ Accidents have no being and existence of their own, except in so far as they receive it from the substance of which they are a modification and actualization. The substance can exist without the accidents, but the accidents cannot exist naturally without the substance; the substance, therefore, is the primary reality in a being, while the accidents are only secondary realities in it. That, however, ‘through which a being is what it is,’ is the *primary* reality in it, namely, the essence. In concrete, individual beings the ‘essences must be, in this stricter sense, the *ultimate intrinsic principle of being*. And since this definition applies only to the substance, and not to the accidents, the ‘essence’ of a concrete, individual being consists in its ‘substance.’ It follows from this that ‘essence’ and ‘substance’ are, so far as their reality is concerned, identical.

However, though really identical in a concrete, individual being, ‘substance’ and ‘essence’ are *conceptually distinct*. The concepts of both are somewhat different, which can be seen from their definitions. The definition given in the preceding paragraph is the definition of ‘essence,’ not that of ‘substance.’ The essence, considered in itself, is this

‘ultimate intrinsic principle of being’; considered in the mode of its being and existence, it exists ‘in itself and not in another as in a subject,’ and that is the definition of substance. While really identical, ‘essence’ and ‘substance’ are thus conceptually different.

SUBSTANCE AND NATURE

A similar situation prevails concerning the concepts of ‘substance’ and ‘nature.’ The term ‘nature’ is taken in many meanings. Very frequently it is used to designate the totality of all objects in the universe, or the sum of all the forces operating in bodies according to the laws controlling these bodies. In ontology, however, we do not speak of ‘nature’ in this sense, except incidentally. Here we speak of the nature of a concrete, individual thing, and the term applies to immaterial as well as to material things. In this ontological sense, we understand *nature* to be the *ultimate principle of all operations* in an individual being.

The kind of activities a thing can perform depends upon the kind of being it is: action follows being (*agere sequitur esse*). Specifically different beings have specifically different activities. Water does not act like gold, nor gold like iron, nor iron like radium, nor radium like argon, nor argon like hydrogen. As long as a thing remains what it is, its activities must remain specifically the same. It is because of this fact that the inductive process of reasoning employed by scientific investigators is a valid form of inference and leads to a valid knowledge of physical laws: since the nature of a specific type of bodies remains the

same, their activities must, under identical conditions, produce identical results, i.e., these bodies must act according to a definite physical law. Given the same cause, the same effect must follow.

The activities of things do not simply happen; they are determined by some principle within the thing itself. Since an infinite regress within the being of a concrete thing is impossible, there must be an *ultimate intrinsic principle of activity*. This determining principle is called its nature. And since there is but one single ultimate principle in each being, namely, the 'essence,' this 'essence' is the 'nature' which determines all the activity of the thing. The essence of a thing, however, is identical with its 'substance.' Hence, the 'nature' of a thing is in reality identical with its 'substance,' because two things, identical with a same third, are identical with each other.

But here, too, there is a *conceptual distinction* between 'nature' and 'substance.' The same essence, considered as the 'ultimate principle of operation' in a thing, is called its 'nature'; and the same essence, considered as something which 'exists in itself,' is called a 'substance.' The three concepts differ in meaning and definition, although they are identical in their reality.

SUBSTANCE AND HYPOSTASIS

Another concept, closely allied to substance, essence, and nature, is that of *hypostasis* (Gr., ὑπόστασις). In Latin it is called *suppositum*. There is no equivalent term in English,

although the word '*supposit*' is employed at times. We will use the Greek word 'hypostasis.'

It has been shown that accidents belong to their substance and inhere in it; accidents, therefore, do not exist completely in themselves. Secondary or universal substances, as expressed in concepts designating species and genera, are communicated to, and predicated of, the individual substances; they also do not exist completely in themselves. Substantial parts belong to the whole of which they are parts; they, too, do not exist completely in themselves. But an *individual, concrete substance* exists completely in itself. By this we mean that it is incommunicable to any other being; it does not belong to another; it is the whole or unit containing all the parts; it is the ultimate reality to which all functions, powers, and perfections of that particular being are referred; it is the possessor of its entire nature; it is self-contained and autonomous, i.e., it controls its own actions independent of any other individual (creatural) being; it is complete in the order of its essence and in the order of its existence: it is, in a word, *sui juris* ('of its own right'), its own possessor.

For example, I perform my own acts and my Ego is the ultimate reality from which they originate and to which they must be referred; my actions are 'mine' and belong to no one else. Hence, I act 'of (in) my own right'; my Ego is *sui juris*. This sort of existence has a special name; it is called 'subsistence.' The phrase '*sui juris*' may be rendered in English as 'self-contained and autonomous.' Subsistence, therefore, is that mode of existence in virtue of which a thing is self-contained and autonomous in its operations.

When we speak of a *suppositum* or *hypostasis*, we mean a *complete individual substance which has subsistence*, i.e., a substance which is self-contained and autonomous (*sui juris*) in its operations. This definition applies to every individual substance as it actually exists in the universe, including every inorganic body, plant, brute, and man.

The fundamental reason why such beings are 'subsistent' is that they are a *single* 'substance,' 'nature,' and 'essence.' It is because of this that they are self-contained and autonomous in their being and existence. Hence, it follows that a hypostasis is nothing but the 'substance' considered as *sui juris*, i.e., as subsistent. And since it is identical in its reality with 'substance,' it is also identical with the 'nature' and 'essence' of the thing. Hypostasis, however, differs in concept from these three, because it includes within its concept the mode of *subsistence*, namely, that the 'substance,' or 'nature,' or 'essence,' is self-contained and autonomous; 'subsistence' is not included in the concept of these others. We see, therefore, that we may call a concrete individual being a 'substance,' an 'essence,' a 'nature,' and a 'hypostasis': they are conceptually distinct, but in reality identical.

SUBSTANCE AND PERSON

The term 'person' is peculiar. There is no question as to what or to whom the term applies; but there is considerable controversy among modern philosophers as to what actually *constitutes* 'personality.' In this connection we do not take 'personality' in its popular sense as the sum of

those qualities of temperament and character which distinguish one human being from another. In philosophy we understand by 'personality' that particular mode of being which makes an individual to be a 'person.' The important question, then, is this: *What specifically constitutes a person?*

The term has been in constant use, and for centuries there never has been any ambiguity in its use and application. In this respect the term 'person' is not vague like the terms 'substance,' 'essence,' and 'nature,' which are rather loose in meaning and are applied in a variety of meanings to many diverse types of things, being used at times in a stricter and at times in a wider sense. When used by philosophy, these terms must always be narrowed down to a specific meaning and defined accordingly, so that they will apply to a very definite group of beings and to no other. In the case of the term 'person,' its use has become restricted to a definite group of beings and to no other. Although the group to which the term is thus definitely known, the exact meaning implied in the term 'person' is far from clear. To arrive at a distinctive definition of 'person,' we must consider the *type of beings* to which the term is invariably applied and, by means of a careful analysis of their nature, discover in them the *specific element* which constitutes their 'personality.'

It is an easy task to designate the *types of beings* to which the term 'person' is or is not applicable, *inorganic* beings like gold, silver, carbon, are never styled 'persons.' Neither do we use the term 'person' when speaking of a *plant*, like a rose, a geranium, a pumpkin. No *brute* is called

a 'person,' no matter how highly developed in the scale of life; thus, no amoeba, fish, reptile, bird, or ordinary mammal, is a 'person.' These types of beings do not possess that specific element which we invariably associate with the concept of 'person.'

Every being, however, *above the level of brute animality is styled a person.* Every *human* being is a 'person,' irrespective of age, sex, color, or condition. A child, even though unborn, is a 'person' in the strict sense of the term, and the courts of law recognize it as a potential heir to an estate. That an octogenarian or centenarian is still a 'person,' need hardly be mentioned. Even deformed and insane people are real 'persons.' A corpse is not called a 'person,' because it is no longer a human being. Hence, from the universally accepted use of the term we must conclude that *living human* beings are 'persons' and possess that specific element which constitutes 'personality.'

God and *spirits* are also 'persons.' It is true that God, in the meaning of the pantheists, of the absolute idealists, and of some pragmatists, can hardly be said to be a 'person'; but these philosophers are a small minority in comparison with the vast bulk of Christian and other peoples and philosophers who have considered God and the angels real 'persons' in a truly philosophic sense. In the traditional sense, and that is the one taken here, God is a 'person' in the highest degree.

From the above it is clear that any kind of being below man is not a 'person,' while man and all beings higher than man are 'persons.' This being the case, the specific element

of 'personality' must consist in something absent in the former and present in the latter; and although men, spirits, and God are so diverse in nature, there must be an element common to them which constitutes them as 'persons.' What is this *common element*, present in man, spirits, and God, which is absent in inorganic beings, plants, and brutes?

It cannot be *materiality*. The spirits and God are not material beings, though man has a material body. It cannot be *life*. Plants and animals possess life, but they are not 'persons.' It cannot be *simplicity of nature*. God and the spirits are simple in nature, while man is a compound of body and soul; yet all are 'persons.' It cannot be *immortality*. God and the spirits are immortal in their essence, while man is mortal. It cannot be *infinite perfection*. God is infinitely perfect, but the spirits and man are entirely finite. It cannot be *substance* or *essence* or *nature* or *subsistence*. All individual beings, from inorganic bodies up to and including God, possess these degrees of reality. Then what is it?

The only discoverable element which is distinctive of God, spirits, and man and which is lacking in all beings below the level of man, is *intellectuality*. Of course, the intellectuality of God is of an infinitely higher order than that found in spirits or man; it is one with all His other perfections, and all His perfections are a single, identical, infinite reality. Nevertheless, the perfection of intellectuality is truly present in God. We are now in a position to state what specifically constitutes a *person*: a person is *an intellectual hypostasis, i.e., an individual, complete, subsistent, intellectual substance*. It is customary to define

a person as a '*rational* hypostasis.' The term 'rational,' however, means 'having reason' or 'having the faculty of reasoning,' and as such does not apply to God; God is an 'intellectual,' but not a 'rational,' being. On the other hand, 'intellectuality' is an attribute which is applicable to God, spirits, and man. We therefore use the term 'intellectual' rather than 'rational' in our definition.

It will be clear from the above that hypostasis may be either non-intellectual or intellectual. If it is *intellectual*, it has the special name of person. Every person is thus a hypostasis, but not every hypostasis is a person. The subsistence of a person has a greater perfection than that of an ordinary hypostasis, because an *intellectual* being is to a far greater extent the possessor and master of itself and of its operations. Since, however, every person is a hypostasis and every 'hypostasis' is really identical with 'substance,' 'essence,' and 'nature' in an individual being, it follows that 'person' is only conceptually distinct from them in man, spirits, and God.

From the definition of 'person' it is evident that the *human soul*, considered by itself, cannot be called a 'person.' The soul is only a substantial part of man, the formative principle in the human compound of body and soul. Only a *complete* intellectual substance is a 'person,' and the soul is an *incomplete substance*. This is also true of a disembodied soul after death. It will always remain an essentially incomplete substance, since its essence demands that it exist together with matter to form the complete substance of man as a compound of body and soul. Hence, *man* himself, but not his soul, is a 'person.'

These distinctions should enable us to obtain a deeper understanding of the ‘nature’ and ‘personality’ of Christ, as expounded in Christian theology. The human nature of Christ is a complete nature, viewed from the standpoint of substantiality and specific perfection; it lacks nothing of the entity found in any other human nature. But it does not subsist; it has not that mode of subsistence in virtue of which it is ‘self-contained and autonomous’ or *sui juris*. The human nature of Christ does not exist in itself and it is not the ultimate possessor of its operations. The Logos or Second Person of the Trinity has assumed this nature and taken possession of it, so that the Logos is the real possessor of all its functions. Hence, Christ’s human nature is a complete substance, but not a ‘hypostasis’ or person.’ There is only *one subsistence or one personality* in the God-Man, and that is the divine personality of the Logos. The human nature of Christ is united ‘hypostatically’ or ‘personally’ with the divine nature of the Logos, so that both together are only one *person*. Christ, therefore, consists of two distinct natures in one person.¹

The concepts elucidated above lead to some important *principles* which occur quite frequently in philosophic discussions, especially among scholastics.

Actions belong to the hypostasis or person. The ‘nature’ of a being is the principle of all its actions. But the nature of an individual, concrete being, as it actually exists in the universe, is always a hypostasis and, if it is intellectual, a

person. This fact is clearly expressed in our judgments and statements about things. We seldom refer actions to the faculties or parts from which they proceed immediately, but to the ultimate possessor of the nature. We say 'I see, I hear, I digest, I think, I drive the car,' although it is the eyes that see, and the ears that hear, and the stomach that digests, and the intellect that thinks, and the hands that hold the steering wheel. Actions are thus attributed to the hypostasis or person. The hypostasis or person is the principle *which* (*principium quod*) performs the action, while the nature is the ultimate principle by *means of which* (*principium quo*) the hypostasis or person performs the action.

Actions participate in the dignity of the person. This means that an action has a higher perfection or value, if performed by a person of a relatively higher nature, and a lower perfection or value, if performed by a person of a relatively lower nature. The intellection of a pure spirit is more perfect than a man's, and God's intellection is infinitely more perfect than a creature's, because the 'persons in each instance is greater in perfection. This is natural. If the actions belong to the person, then the dignity of the person is reflected in everything that proceeds from the person, and the actions participate in the dignity of the person.

For this reason the infinite dignity of the Logos or Second Person of the Trinity confers an *infinite* dignity or value upon the actions of His *human* nature. This does not mean that the physical actions of the finite human nature of Christ ever become

physically or entitatively infinite; but it does mean that the entitatively finite actions of Christ have an infinite *value*, because performed by an infinite Person.

This also explains why it is possible to predicate seemingly contradictory things of the person of Christ. It is the *person* which possesses the *nature* and, through the nature, the *actions*. Hence, the activities and attributes of both the divine and human natures in Christ must be predicated of the selfsame person, the *Logos*, and the Logos, therefore, is theandric, both God and man. The Logos as God, is eternal, immutable, infinite; as man, temporal, mutable, finite. As God, He cannot suffer and is immortal; as man, He suffered and died. He suffered and died in His human nature, not in His divine nature. Of course, these things cannot be proved on philosophic grounds; but neither can they be disproved. These facts rest on revelation, not on experience.²

THE CONSTITUTION OF PERSONALITY

The specific element which constitutes a 'person' has become one of the most mooted questions in modern philosophy. The classic and traditional explanation through the centuries up to recent times has been that a 'person' is an intellectual hypostasis, i.e., a complete, individual, intellectual substance, self-contained and autonomous (*sui*

juris). Philosophers and psychologists of a phenomenalist trend object to this view very strongly.

Phenomenalists admit the existence of phenomena, but deny the objective validity of the concept of 'substance.' Of course, if there are no substances in this world, a person is not a substance and the definition of 'person' as a substance is wrong. Driven by their denial of the reality of substance to seek a different explanation of 'person' and 'personality,' they could find nothing in man to constitute 'personality' but his internal, mental states. And since man is a person, while the brute is not, the mental states which constitute personality must be such as are found only in man, namely, the self-conscious states. Man is conscious of his Ego, while the brute manifests no self-consciousness. Hence, most modern philosophers, aside from the scholastics, claim that 'personality' consists in *self-consciousness*, in the *conscious Ego*. As William James puts it: "The passing thought is itself the thinker."

We reject this view as unsatisfactory. In connection with this problem it must be borne in mind that the real question is: What *meaning* must be attached to the term and concept of 'person' and 'personality'? One thing is certain from the start: every human being is called a 'person.' This is universal usage, and we must find the precise element in man which constitutes his 'personality.' We contend that 'self-consciousness or the 'conscious Ego' is not this distinctive element.

Evidently, if that which *constitutes* 'personality' is absent from a being, then that being is not a 'person.' The opponents assert that personality consists in self-

consciousness. Consequently, if a human being lacks self-consciousness, it is not a person. A human being, however, is not always conscious of self. Children, during the entire prenatal state, and after birth for a considerable period of time, have no reflex knowledge of themselves; they are not conscious of self or Ego. Perpetually insane people and idiots of an extreme type have no real consciousness of self. Human beings under the influence of some strong narcotic are totally unconscious and have, therefore, lost their self-consciousness for the time being. Deep sleep and intense distraction deprive people of all conscious contact with their surroundings and also of the consciousness of their Ego for a while. Similarly, sickness or traumatic shock often render human beings oblivious of themselves for weeks and even months at a time.

Now, if 'personality' were really and formally constituted by 'self-consciousness' or the 'conscious Ego,' we would be constrained to conclude that human beings in such conditions are *not persons*, because the *constitutive element* of 'personality' is absent. This, however, would do violence to the concept of 'personality.' Only a desperate extremist would assert that a child before birth and up to probably two or more years of age is not a 'person.' It is certainly false to claim that normal human beings are 'persons' only *when awake*, and cease to be 'persons' for the period of sleep or intense distraction. Every human being is a 'person' *as long as he lives*. This is clear from the fact that the subject of law is the human 'person,' and the law applies to every human being, whether born or unborn. Only 'persons' can demand a reparation for injury or

damage done to them by their fellow men. Shall we then maintain that people in sleep or under an anaesthetic may be injured with impunity for the mere reason that they are not self-conscious and are, therefore, not 'persons'?

Furthermore, *self-consciousness* is an *operation*, a *function*. According to our opponents, this passing state or function would constitute 'personality.' They must assert this, because they do not admit the existence of anything like a substance. However, we have already shown that *substances exist*. The reason for their opposition, therefore, is nullified. We have also shown (and it will be shown more clearly in psychology) that underlying all internal states and functions there is a substantial basis, a substance, which *possesses* these transient modifications and to which they must be ultimately referred as to their originating principle. These mental states and functions are phenomena, accidents; as such they must inhere in an *Ego*, and this Ego is the ultimate reality within us, identical and permanent amid all changes. The Ego is, therefore, a *subsisting substance*, existing in itself and not in another as in a subject.

This idea of a *subsisting substantial Ego* alone coincides with our concept of a 'person.' The difference between the brute and man as subsisting substances lies in this that man is a person,' while the brute is not. This difference between man and brute is an *essential* one; and, being essential, it is not merely an accidental difference, but a substantial one. The difference between them cannot consist in 'subsistence' as such, because both are subsistent and both are substances. The essential difference between man and

brute consists precisely and formally in this, then, that man is an intellectual subsistent substance, while the brute is a non-intellectual subsistent substance. That is the *specific difference* between them and this difference is not accidental, but essential. But what does this mean, if not that man is a 'person,' because he is an individual, complete, *intellectual* substance, self-contained and autonomous? That, however, is the meaning we attach to the term person' from the beginning of the discussion.

This interpretation alone will avoid the absurdities of the theory of self-consciousness as constituting 'personality.' Man, then is a 'person' by the very fact that he is a man; and he remains such as long as lives, from the first moment of his life until the moment of his death, whether he be born or not, whether he be conscious or unconscious of self. Hence, the concept of 'personality' is identical with that of an *intellectual subsistence*, and the concept of 'person' is identical with that of an *intellectual hypostasis*.

Some philosophers attempt to evade these conclusions by asserting that a human being may remain *habitually* self-conscious and thus remain a 'person' at all times, even if he lose actual self-consciousness through sleep, disease, narcotics, etc. This view, however, will not remove the difficulty. Something is said to be 'habitual' when it is based on a habit, and a habit is usually the result of *frequently repeated separate acts*. However, can an unborn child be said to have 'habitual' self-consciousness? This would presuppose that it had performed repeated acts of self-consciousness from the very first moment of its existence and had thereby *acquired* habitual self-consciousness. This

is a necessary conclusion, because even an unborn child is a true 'person.' But who will not understand that such an assumption is purely arbitrary? No one can reasonably assert that an unborn child performs such acts. Besides, a habit that is acquired through repeated acts can also be *lost* through the omission of such acts; then a human being would cease to be a 'person.' That, however, is contrary to the universal conviction that *every* human being is a person at all times. Hence, habitual self-consciousness cannot constitute a 'person.' Consequently, the thesis stands: *A person is an intellectual hypostasis*, i.e., it is an individual, complete, *intellectual* substance, self-contained and autonomous.

To sum up: in a concrete, individual being, as it actually exists, the distinction between 'essence,' 'substance,' 'nature,' 'hypostasis,' and (in the case of man, spirit, and God) 'person' is only *conceptual, not real*. In reality they are one identical entity. Since, however, there is a foundation in the beings themselves for making a distinction between them in concept, they differ from each other by a *virtual* distinction with a foundation in the reality itself.

SUMMARY OF CHAPTER XVIII

The concepts of 'substance,' 'essence,' 'nature,' 'hypostasis,' and 'person' are closely akin in meaning.

1. *Substance and Essence.* In a general sense, 'essence' is that through which a being is just what it is. Since substances and accidents are beings, each accident as well as substance has its own essence. In a *strict sense*, we take the concrete, individual being, consisting of a substance and numerous accidents; and in this sense, the *substance alone* is the essence of the thing, because the accidents of such a being are not absolutely required and are not absolutely sufficient to make this being to be what it is. 'Essence' is, therefore, identical in reality with 'substance,' with a virtual distinction between the two.

2. *Substance and Nature.* By 'nature' we mean the ultimate principle of all operations in a concrete, individual being. Since the individual being is a natural unit of entity and activity, it can have but one ultimate principle of both its entity and its activity. This is the 'essence,' which is identical with the substance of the thing. Hence, in reality 'nature,' 'essence,' and 'substance' are identical, with a virtual distinction between them.

3. *Substance and Hypostasis.* Neither the accidents, nor secondary substances, nor substantial parts, exist completely in themselves; they exist in the concrete, individual substance, and it is the latter which exists completely in itself in such a manner that it is self-contained and autonomous, i.e., *sui juris*. This mode of existence is

called 'subsistence.' A *suppositum* or *hypostasis*, therefore, is a complete, individual substance that has subsistence, i.e., one which is self-contained and autonomous. And since it is the 'substance' or 'essences or 'nature' which has being and existence, the 'hypostasis' is in reality identical with them, with a virtual distinction between them.

4. *Substance and Person.* The term 'person' is never applied to any being lower in nature than man. Men, spirits, and God are always considered to be 'persons' and to have 'personality.' That which constitutes a 'person' must, therefore, be some specific element found in men, spirits, and God. The only discoverable element found in men, spirits, and God, and absent in inorganic bodies, plants, and brutes, is *intellectuality*. Hence, a 'person' is an *intellectual hypostasis*, i.e., a complete, individual, subsistent, intellectual substance. Every person is thus a hypostasis, but not every hypostasis is a person. From this it follows that 'person,' 'hypostasis,' 'substance,' 'essence,' and 'nature' are identical in their reality, with a virtual distinction between them.

Two principles are important: actions belong to the hypostasis or person; actions participate in the dignity of the person.

5. *The Constitution of Personality.* Modern philosophers, especially psychologists of a phenomenalist trend of thought, contend that *self-consciousness* or the *conscious Ego*, as a passing mental state, constitutes 'personality.' This is erroneous. If this were the formal, constitutive element of personality, then, this element being absent in a being, this being could not be called a 'person.'

Man is a 'person' at all times and in all conditions; but man is not always conscious of self or Ego. This is the case with infants, especially those as yet unborn; with perpetually insane people and idiots of an extreme type; with human beings under the influence of a strong narcotic, of sleep, of intense distraction, of sickness, and of traumatic shock. Hence, self-consciousness is not the constitutive element of 'personality,' because these people are real 'persons.'

Furthermore, self-consciousness is a *function* which is possessed by the *Ego*. The function is a passing mental state; the Ego remains. Hence, the Ego is an intellectual hypostasis. Intellectuality' is the specific difference between man, spirit, God, and the lower forms of brute, plant, and inorganic body. A 'person,' therefore, is an *intellectual hypostasis*.

Chapter 19

QUALITY

ONTOLOGY DOES NOT TREAT OF ALL THE SINGLE CATEGORIES of accident. Ontology is *General* Metaphysics and as such concerns itself with those phases of being which are, as a rule, found in both material and immaterial beings. Accidents found in material beings only or in immaterial beings only do not belong to ontology proper. Immaterial reality, such as the human soul, belongs to psychology; corporeal reality, such as quantity, place, time, posture, and habitus, belongs to cosmology. 'Quantity,' for example, presupposes material parts side by side in a body; 'place' and 'space' rest upon the quantity and extension of bodies; 'time' is the element of successive duration in bodily movements. These accidents, therefore, belong to cosmology, the philosophy of bodily or material beings. 'Posture' and 'habitus' are also accidental determinations of bodies, and their treatment is thereby excluded from ontology; from a philosophic standpoint, however, they are so unimportant that they hardly deserve special treatment.

It is different with the remaining accidents of *quality, relation, action and reaction* (passion). They are really general in character, because they affect immaterial as well

as material beings. These will be examined in the following chapters.

THE CONCEPT OF QUALITY

Strictly speaking, quality *cannot be defined*. The only proximate genus which could be used in such a definition would be 'accident.' But, as was intimated before, the concept of 'accident' can hardly be predicated of its inferior members in a strictly univocal manner; it is, rather an *analogous concept*. Taken in a *wide* sense, 'quality' means any kind of modification. The term is used in a very loose way to signify almost anything, even though it be a part of the essence, which can be predicated of a subject in an adjectival form. Thus, we say the 'Man is rational.' Here 'rationality' is considered as a quality of man, although it is really essential and one with man's concrete substance. Similarly, we say that 'a brute is sentient, a plant is living.' Here, too, 'sentiency' and 'life' are predicated of their subjects in an adjectival form as qualities, but they are not qualities in the sense of 'quality' as a categorical accident. In this wide sense all *specific differences*, distinguishing one species of substance from another, are considered to be qualities. In fact, since *any kind of accident* is, in a way, a modification and qualification of substance, all accidents, even quantity, are frequently spoken of as being 'qualities' of things. This, of course, is not the meaning of quality when we speak of it as a separate and distinct *category*.

Taken in a *strict* sense, quality is a category distinct from the category of substance, quantity, relation, and the

others. *Aristotle* describes it as follows: “By ‘quality’ I mean that in virtue of which people [things] are said to be such and such.”¹ A quality always presupposes a thing as being constituted in its proper species, as completed in the line of its substantiality and specific perfection. A quality determines a completed substance in some accidental manner, so that the substance is now ‘such and such’ by the addition of some modifying entity. Creatural substances have certain *potentialities* which must be actualized and completed if these substances are to attain the fullness of their being; and it is the qualities which supply, at least partly, the *actualization* and *completion* of such natural tendencies.

Aristotle’s description is too vague to be of much value. Subsequent philosophers have attempted a more definite wording in their descriptive definition of quality. A definition which serves the purpose is this: *A quality is an absolute accident completing and determining a substance in its being and in its operations.*

Aristotle² enumerates *four distinct types of quality*: habit and disposition (ἔξις καί διάθεσις); natural capacity and incapacity (δύναμις καί ἀδυναμία); affective qualities and affections (παθητικάί ποιότητες καί πάθη); form and figure (σχῆμα καί μορφή). He admits that there might be some qualities not included in this division, but maintains that most qualities, properly so called, will find a place in these groups.³ It will be noticed that each group consists of two members. The four groups can readily be reduced to two main classes: entitative and operative qualities. This is

indicated in the definition of quality, when we say that it modifies a substance in its 'being' and in its 'operations.'

HABIT AND DISPOSITION

A habit is a comparatively permanent quality disposing a thing well or ill in its being. When it is stated that a habit is 'comparatively permanent,' the meaning is that it must be stable relative to the nature of the thing which has this habit. That, of course, differs with different beings. The life, for instance, of some insects lasts but a week or even a day. Something may be relatively permanent for it in its short life, which would be relatively transient in the much longer period of life for some other being. The beauty of such an insect would be an entitative habit, perfecting and completing it in its being. If a human being's beauty lasted for a week or a day only, it would be transient. Habits, however, need not always be a perfection of the substance: they may dispose a thing well or ill in a permanent manner. Many habits dispose a thing 'well': for example, beauty and health in a human body, knowledge in the intellect, virtue in the will. Other habits dispose a thing 'ill': for example, chronic catarrh or rheumatism in a person, ugliness or deformity in a body, forgetfulness in the intellect, vice in the will.

If this quality is not permanent, but *relatively transient to the nature* of the thing which possesses it, it will either dispose the thing temporarily well, and then it is called a *disposition*, or it will dispose it temporarily *ill*, and then it is called an *indisposition*. Thus, the easing of pain through

morphine, the feeling of well-being after a meal, the rally of a seriously wounded or dying person, are naturally temporary in character and dispose the patient 'well'; this is a 'disposition.' A toothache, a headache, a sprained ankle, a carbuncle, acute appendicitis, are qualities, temporary in character, which dispose one 'ill'; they are 'indispositions.' If these dispositions or indispositions become inveterate in the course of time, so that they are difficult to remove and are comparatively permanent in the subject, they become 'habits.'

So far we have taken 'habits' and 'dispositions' in a wider sense, as permanent or temporary *entitative* states. *Operative habits* are 'habits' in a stricter meaning of the term. Operative habits are stable qualities disposing a being ill or well in the *operations* of its faculties. Such a habit gives a definite direction to the acts of a faculty, a determination in virtue of which the faculty *tends* to act in one manner rather than in another. Every repetition of the act increases this tendency and makes the subsequent operation of the same kind easier. What was done in the beginning as the result of conscious effort, now becomes almost automatic, 'and the faculties carry out their respective acts with little external stimulation or none at all. We perceive the working of operative habits in the complicated acts of walking, speaking, typewriting, playing a musical instrument, memorizing, etc. One need but recall to mind the painful efforts of the tyro on the piano and compare them with the ease, grace, and proficiency of the same person after years of diligent application to the art, in

order to realize the difference between the single act and the habit.

Not all faculties are capable of being determined by habits.

The very nature of habit, as a quality *determining* a faculty to a definite mode of operation shows that habit presupposes a faculty which is *indifferent* to a *variety of actions*. It is only when a faculty is as such indeterminate to various kinds of actions that it is capable of further determination from a habit. A faculty which is already determined by its very nature to act in such or such a manner can receive no further determination from a habit, because no inclination and tendency is as strong as one given through the necessity of a being's nature. Thus, the natural forces of inorganic elements and bodies work forever in the same manner. Gravity, for instance, attracts the stone with the same force after the thousandth time as at the very first time; it gains nothing by repeating the action. Chemical affinity, electricity, light, steam, magnetism, heat, etc., acquire no increased facility or tendency through repetition. So, too, plants and animals are determined in their operations by their very nature; under the same conditions they will, if left to themselves, act in the same way.

Hence, only such things can properly be the subjects of operative habits as are *free in their activities*, because they are intrinsically indeterminate. The *free will* is primarily capable of habits. We know from our own experience that by repeated actions we form certain habits of virtue and vice which, once they have gained a foothold, are difficult to

change. The *intellect* is also capable of habit, in so far as the will can apply it in different ways to its object; we see this in the habit of knowledge. The *sensitive powers* of man, considered in themselves, are incapable of habit, because they have a necessary direction toward their respective objects. Since, however, they are under the control of the will, they are, indirectly, capable of being perfected by habit. Through intensive exercising along certain lines, man can 'train' his eye, his ear, his imagination, and so forth.

Brutes cannot acquire habits in the strict sense of the term. Their organs are directed by natural necessity toward determined acts. Their movements are regulated by sense-perception and sense-impulse, both of which have no choice in the performance of their natural functions. Under the influence of man's direction, especially through the administration of pleasure and pain, they can be 'trained' to perform actions which *of their own accord* they would never perform. But this seems to be nothing more than forcing their memory to associate certain pleasures and pains with the performance or omission of certain actions, and this pleasure or pain drives the animal *with necessity* toward the performance or omission. Hence, strictly speaking, only rational powers are capable of habits; under their influence other powers can, indirectly, also acquire habits.

Some habits are *given by nature* itself. It would be more correct to say that nature gives the beginning of habits, rather than habits themselves. Thus, philosophers speak of the *habitus principiorum*, the 'habit of principles,' as present in the mind from the start; they mean thereby that

man's mind has a natural facility and inclination to understand and form fundamental principles of thought. Such are the Principles of Identity, Contradiction, Excluded Middle, and Sufficient Reason.

Other habits are *acquired* through the *frequent repetition* of the same acts. What has been said in general about habits, refers to this class. Examples would be the habit of language, knowledge, walking, writing, etc.; of virtue, like kindness, patience, truthfulness, chastity, temperance, etc.; of vices, like cruelty, mendacity, immodesty, laziness, drunkenness, etc. Once acquired, they are relatively stable.

Theologians also speak of *supernatural* habits. They exceed the limits of nature and can be acquired only as the gift of God. Such would be the divine virtues of faith, hope, and charity; also infused knowledge and the gift of tongues. Supernatural habits are, of course, outside the scope of philosophy.

CAPACITY AND INCAPACITY

By *natural capacity* we understand the *proximate accidental principle of operation, toward which (operation) it is specifically directed*. It is a 'principle' of operation, because it produces the operation. It is a 'proximate' principle, in order to distinguish it from the remote adequate principle of operation, which is the nature or substance. Both nature and natural capacity are principles of operation in a thing, but in a different way. The nature or substance is the ultimate principle of operation, in as much

as the operation flows directly from the capacity or faculty and the capacity or faculty is the immediate principle 'through which (*quo*)' the nature or substance acts. The natural capacity is a 'principle' of action, and that distinguishes it from a 'habit.' The capacity or faculty is the immediate source of activity, while the habit merely modifies the faculty in such a manner that the faculty performs its operations with greater ease and speed. Without the faculty there can be no operation and no habit; but without the habit, the faculty would still be capable of performing its operation, though not with ease and speed. A natural capacity is said to be an 'accidental' principle of operation, so as to distinguish it from a substantial part in a being; thus, the hand is an instrument of action, and as such a principle of operation, although it is not a faculty or capacity. By 'operation' we mean the act which the faculty performs. This may be transient, as when a ballplayer throws a ball; or immanent, as when the intellect thinks and the will desires. The capacity or faculty must be 'specifically directed' toward a certain action, in order that it may be said to be the faculty of this action. Thus, the will is specifically directed toward appetitive acts and not toward intellectual acts, although the will frequently commands the intellect to act; the will, therefore, is not the faculty for intellectual acts, but for appetitive acts. Faculties or natural capacities thus make a nature prepared and fit to act, even though it does not actually exercise them; man, for instance, has an intellect and will capable of action, irrespective of the fact whether he actually thinks and wills or not.

Inorganic beings have many natural capacities. Such are gravitational attraction, electromotive power, chemical affinity, cohesion and adhesion, flexibility, elasticity, etc. In *vegetative* beings we observe the powers of nutrition, growth, and reproduction. *Sentient* beings have these vegetative powers and also the special faculties of sense-perception, sense-appetition, and locomotion. *Rational* beings have the spiritual faculties of intellect and will; and man, since he is a rational animal, also possesses the vegetative and sentient powers characteristic of plants and animals. What has been termed 'subjective' or 'real' potentiality in the previous discussion on 'potency' and 'act,' belongs to this class.

More or less in opposition to these natural capacities are the incapacities. By an 'incapacity' we do not mean the total absence of a faculty, because that would no longer be a faculty of action. By *incapacity* we understand *an existing faculty in a weakened or unfit condition*. The worn spring of an automobile, having lost a great amount of its resilience, would be an incapacity. A weak dry cell in a flashlight would be another instance of incapacity. A drooping flower, a drought-affected tree, a mildewed patch of grain, manifest a diminished power of vegetative function; but they still are living beings. Lameness of limb, astigmatism of the eyes, and other functional deficiencies, do not deprive the animal completely of its faculties and their use, but they render it more or less unfit for action. Psychopathic conditions, like insanity, idiocy, and sexual perversion, are at times the result of physiological abnormalities; they are incapacities

which hinder the intellect and will in their proper functioning.

AFFECTIVE QUALITIES AND AFFECTIONS

Affective qualities and affections are qualities which *produce, or result from, some accidental sensible alteration*. If this alteration is relatively permanent, it is an *affective quality*; if it is more or less ephemeral in character, it is an *affection*. The term 'affection,' as should be obvious from the context, does not mean love or devotedness; it is used in the sense of 'affecting' or 'being affected by' something. It was stated in the definition above that affective qualities and affections 'produce or 'result from' alterations. Both types may be the *cause or effect* of such alterations in a sense-organism. Hence, any sensible alteration involved in sense-perception or sense-appetition belongs to this class. This includes the sensible qualities of bodies, like color, flavor, odor, sound, temperature, the feel of smoothness and resistance, etc.; the sensible passions and emotions, like anger, list, pleasure, pain, etc.

Taking the terms in the above-mentioned meanings, a *permanent* red color of the cheeks, due to a systemic condition of the body, would be an 'affective quality'; such, too, would be the natural color of the skin in the various races of mankind, the blue color of the violet, the sweetness of sugar, the sourness of the lemon, the fragrance of the rose, the obnoxious odor of asafoetida, etc. If such qualities are temporal and *transient*, they are 'affections.' The blush of shame, the pallor of fear; heat, color, moistness, dryness,

hardness, softness, etc., when of short duration or easily removed; the states of sensation, as they exist in the organs of sight, hearing, taste, etc.; brief spells of anger, fear, grief, hunger, thirst, and so on: these are various kinds of 'affections.'

It was stated that these terms apply to accidents which *cause* such changes as well as to accidents which are the *effects* of such changes. This will be noted in the illustrations enumerated. Thus, the 'red' of the rose and the 'sweetness' of the sugar cause the sensation of 'vision of red' and of the 'taste of sweetness' in the perceiver; they are the *causes* of corporeal changes in the perceiver and are affective qualities for that reason. On the other hand, the 'perception' of red and of sweetness is the *effect* of the red color in the rose and of the sweetness in the sugar, in as much as the qualities of the rose and of the sugar produce sensations in the organs of the perceiver; this 'perception' is, therefore, an 'affection.' And this holds true of the other affective qualities and affections.

The *soul* also has its affective qualities and affections. According to Aristotle: "That temper with which a man is born and which has its origin in certain deep-seated affections is called a quality [affective quality]. I mean such conditions as insanity, irascibility, and so on; for people are said to be mad or irascible in virtue of these. Similarly, those abnormal psychic states which are not inborn, but arise from the concomitance of certain other elements, and are difficult to remove, or altogether permanent, are called qualities, for in virtue of them men are said to be such and such. Those, however, which arise from causes easily

rendered ineffective are called affections, not [affective] qualities. Suppose that a man is irascible when vexed: he is not even spoken of as a bad-tempered man, when in such circumstances he loses his temper somewhat, but rather he is said to be affected. Such conditions are therefore termed, not [affective] qualities, but affections."⁴

What Aristotle here remarks about one or the other quality of the soul, is especially true of the *temperaments* of people. Four types of temperament are usually mentioned — a division that is more convenient than accurate. They are: the choleric, the phlegmatic, the sanguine, and the melancholic. *Choleric* persons are energetic and vigorous in action, strong-willed, ambitious, tenacious of purpose, not easily discouraged, capable of overcoming great obstacles, quick-tempered, and opinionated. *Phlegmatic* persons are unhurried in their movements, lethargic in disposition, slow of decision, unruffled in temper, indolent, difficult to arouse, unimaginative, easily discouraged in the face of difficulties. *Sanguine* people are lively, enthusiastic, imaginative, witty, sociable, quick in movement and speech, eager for novelty, prone to flightiness, easily led by appeal, adventurous, and inclined to follow romantic ideals. *Melancholic* persons are introspective and brooding, sad of disposition, inclined to see the dark side of life, given to discouragement, easily hurt in their feelings, unforgiving and unforgetting, suspicious of motives, obdurate in judgment, eccentric in conduct, aloof in social life. The very complexity of temperaments is an indication that they rest upon a variety of affective qualities which are partly bodily and partly mental. While the general types are fairly clear and plainly

recognizable, there is in the vast majority of cases a blending of temperamental characteristics; this again is due to the fact that they are the composite result of a number of affective qualities existing in an individual person.

In all instances of affective qualities and affections, a certain amount of *sensible alteration* or change is noticeable. This is but natural, since chemical, physical, and mechanical energies play a prominent role in all operations of sense-perception and sense-appetition, either directly or indirectly, either as causes or as effects. Sentient life is strongly influenced by these energies and is also instrumental in releasing these energies. But wherever energy is at work, alterations or changes are bound to be involved. Hence it happens that affective qualities and affections either *produce* such alterations or *result* from them.

FORM AND FIGURE
